While it is to be regretted that a stronger case for dentistry as a health service could not have been presented, there is no doubt that "this monograph will be of value to the dentist, the the physician, the health worker and the lay person who desire a total view of the present status of this profession and its place in a broad health service."

A Practical Handbook of Midwifery and Gynæcology for Students and Practitioners. By W. F. T. Haultain, O.B.E., M.C., B.A., Obstetrician and Gynæcologist, Royal Infirmary, Edinburgh, and Clifford Kennedy, M.B., Ch.B., F.R.C.S., Assistant Obstetrician and Gynæcologist, Royal Infirmary, Edinburgh. Third edition. Cloth. Price, $6. Pp. 388, with 47 illustrations. William Wood and Company, Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This is a small book which presents chiefly in outline form the essentials of obstetrics and gynecology. In the United States such reference books for students are no longer popular, but apparently in Great Britain they are. Since there was a ten year interval between the second and the present edition, due to the war, a considerable part of the book was rewritten and a few new chapters were added. The subjects are well presented and the advice given in regard to treatment is conservative and proper. There are only forty-seven illustrations in the entire book and in the recent edition many of them should be replaced by more important ones. In a practical handbook of limited size attempting to cover two important specialties the following illustrations are irrelevant; the development of the ovum (highly diagrammatic), malacosteon pelvis, Naegele's pelvis, Roberts' pelvis and five illustrations of instruments used for destroying a baby. It is also questionable whether gynecologic operations should be described and illustrated in a small handbook. Two illustrations show an operation for expanding the vaginal outlet. This operation is a rarity. In the section on artificial respiration the authors fail to mention the tracheal catheter, which is one of the simplest and most effective means of initiating respiration in the newborn. The authors consider the axis-traction forceps, particularly the Milne-Murray type, to be the perfect instrument. In the United States few obstetricians use an axis-traction forceps even in difficult cases. In the treatment of puerperal sepsis there is no mention of penicillin, presumably because this section of the book was written before the introduction of the drug. However, penicillin is mentioned in the treatment of gonorrhea. Treatment is not outlined for syphilis, although the pathology and diagnosis of this disease are described.

Aside from these minor criticisms the book should prove most helpful to students and practitioners who prefer to study subjects in outline form. The book is easy to read, and the type is clear.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

ANESTHETIC DEATHS

To the Editor:—What is the number of deaths which occur annually during general anesthesia? What is the number of deaths which occur annually during general anesthesia for tonsillectomy? What is the number of deaths under spinal anesthesia? John S. Mikell, M.D., Tucson, Ariz.

Answer.—Definite answers to questions of this type are impossible (Safety of Anesthetics, Queries and Minor Notes, The Journal, Dec. 21, 1946, p. 1045). A recent paper by Bishop (Operating Room Deaths, *Anesthesiology* 7:651 [Nov.] 1946) is pertinent. This paper, with the references accompanying it, together with the remarks on Morbidity in Maxson's textbook (Spinal Anesthesia, Philadelphia, J. B. Lippincott, 1938, p. 242) offer some statistical information and pertinent comment. The figures tabulated by Bishop from the U. S. Bureau of Census (542 deaths during tonsillectomy and adenoidectomy among 6,250 deaths during operations occurring over a period of ten years) are difficult of evaluation because the total number of operations done during the ten years is not available. Neither is information available as to the details of anesthetic and operative procedure employed. Unquestionably the death rate during general anesthesia for tonsillectomy and during spinal anesthesia is relatively high. Whether a death in either instance is due to the anesthetic method per se or to inexpert management, both surgical and anesthetic, is often difficult to determine.

An unfortunate concept exists in the minds of many physicians that tonsillectomy under general anesthesia is a minor procedure demanding only a minimum of professional skill and experience either anesthetic or surgical. Much the same attitude exists in some localities regarding spinal anesthesia. Surgeons may administer a spinal anesthetic themselves, or permit their assistant to do so, and then operate on the patient with little consideration for the technic of administering the agent or for the supervision of the patient's condition during the effect of the drug. The experienced anesthetist, on the other hand, looks on these two procedures as technically exacting, requiring the maximum of skill and experience to make them safe.

HYPERHIDROSIS OF THE FACE

To the Editor:—A man aged 29 complains of either increased sweating on the right side of the face and head or decreased sweating on the left side (the second possibility seems more likely). Sweating elsewhere on the body is normal, although it is excessive in hot weather. Signs of Horner's syndrome are absent including ptosis of the lid, flushing and inequality of the pupils. Physical and neurologic examination are negative. Please discuss the etiology of this condition. M.D., Ohio.

Answer.—Various possibilities exist to account for this man's complaints. Hypersensitivity to various articles of food, such as chocolate, or other agents, such as inhalants, may be responsible. Hypersensitivity to histamine as in the Horton syndrome may be considered. In this syndrome headache may be present with or without flushing, tearing and sweating. The symptoms and signs are usually present only on one side. Various psychiatric conditions may be present, such as anxiety states. On the other hand, an organic disease of the upper thoracic cord may be present, such as syringomyelia or a tumor of the cord. These affect the cells of origin for preganglionic fibers supplying the sweat glands of the face. The patient should be given neuropsychiatric intensive study.

EXFOLIATIVE DERMATITIS AFTER CHRYSOTHERAPY

To the Editor:—Please discuss treatment of a patient with extensive exfoliative dermatitis of six months' duration following gold salt therapy for rheumatoid arthritis. Nicotinic acid was tried but was discontinued because of uncomfortable reactions. Alan A. Bassett, M.D., Little Current, Ont.

Answer.—In cases in which the exfoliative dermatitis following the use of gold salts has persisted four or more months, treatment should include measures recommended for exfoliative dermatitis in general as outlined by modern textbooks on dermatology (for example, Ormsby, O. S., and Montgomery, Hamilton: Diseases of the Skin, ed. 6, Philadelphia, Lea & Febiger, 1943, pp. 198-211). At this late date it is not likely that the use of BAL (British Anti-Lewisite) or any other metallic antidote will have much effect.

Symptomatic treatment will need to be carried out for a long time. The following measures are regarded as useful:

1. A soothing bath should be taken once or twice daily. The patient should not remain in the bath long enough to permit the skin to become soggy or macerated. Directions for a soothing bath follows:

Cook 2 cups of bulk oatmeal in 1 quart of water for thirty to forty-five minutes in a double boiler. Allow to cool for fifteen minutes, then add ½ cup of baking soda. Pour the entire mixture into a gauze bag and tie shut. Place in a bathtub one half to three fourths full of water at about 90 to 96 F. The patient may stay in the tub a half to two hours, expressing the oatmeal mash through the gauze and applying it over the body. Wash off the mash thoroughly before leaving the tub. Dry by patting, not by rubbing.

2. A mild emollient like olive oil or olive oil in lime water may be applied every one or two hours.

3. As the process becomes less acute one should apply a mild ointment with a heavy base such as zinc oxide and 3 per cent icthammol. Measures 1 and 2 should be continued also.

Thereafter time is the main factor. Healing may take weeks or months. The residual pigmentation may persist for months or permanently.

INCIDENCE OF POSITIVE SEROLOGIC TESTS FOR SYPHILIS

To the Editor:—What is the incidence of positive Wassermann tests as found in private physicians' offices, where routine blood Wassermann or Kahn tests are taken? What is the present day conception as to whether patients with positive blood reactions should be treated? Should treatment be administered to patients with positive Kahn tests without clinical symptoms if they are over 40, 50 or 60 years of age? C. Raymond Arp, M.D., Atlanta, Ga.

Answer.—The incidence of positive serologic tests for syphilis found in the private practice of medicine will vary enormously, depending on a variety of factors. Some of these are the geographic location of the physician (the incidence of syphilis is highest in the Southern and Southeastern states, lowest in the Northern and Northwestern states), the character of the physician's clientele (the incidence of syphilis is highest in patients in the lower socioeconomic levels, especially Negroes) and the special character of the physician's practice (for example, a dermatologist or a urologist might confidently expect the accidental discovery of greater numbers of patients with syphilis than an orthopedist).

The treatment of patients of any age discovered routinely to have positive serologic tests for syphilis depends on a large number of factors, all of which are discussed in such modern textbooks as Modern Clinical Syphilology by Stokes, Ingraham and Beerman (ed. 3, Philadelphia and London, W. B. Saunders Company, 1944) or The Modern Treatment of Syphilis by Joseph Earle Moore (ed. 2, 3d printing, Springfield, Illinois & Baltimore, Charles C Thomas).

CESAREAN SECTION AND REPAIR OF VENTRAL HERNIA

To the Editor:—A secundipara has now been pregnant four months. Her first pregnancy was eighteen years ago. Since then she has had a perineal repair and suspension of the uterus. After the suprapubic operation she developed a large ventral hernia. Is a cesarean section indicated with repair of the hernia at the same time or should the patient be allowed to go into labor and the hernia repaired at a later date? Lowell G. Hunter, M.D., Milan, Ind.

Answer.—It is not sound obstetric judgment to perform a cesarean section in order to carry out other surgical procedures at the time of delivery. Therefore it is not proper to perform a cesarean section simply because it is desired to perform a sterilization, remove a so-called chronic appendix or, as in the case described in the query, repair a postoperative hernia. There are several reasons for this. First, the risk of death following cesarean section is distinctly higher than it is for vaginal delivery even when the operation is an elective one. Second, the additional operation may increase the hazards of cesarean section because of the increased likelihood of infection. Third, in the case of an extensive postoperative hernia the additional length of the trauma of operation and the prolonged time of anesthesia undoubtedly will increase the risk of the laparotomy. This patient should be permitted to deliver from below and, because of the previous perineal repair and the eighteen year interval, an episiotomy should be done. The ventral hernia may be repaired after the baby is a week old, but it would be preferable to postpone this operation for a few mon

VISUALIZATION OF GALLBLADDER

To the Editor:—A woman at one time had symptoms of mild subacute cholecystitis, chronic arthritis of the spine and high blood cholesterol (330 mg. per hundred cubic centimeters). She was given a low cholesterol diet for several weeks with resultant loss of a few pounds in weight. Recently after complete examination by another physician including gastrointestinal roentgenograms, a gallbladder visualization test and x-rays of the spine, she was told that her only trouble was chronic arthritis of the spine. It was further stated that she never had had any gallbladder disturbance because, if she had the diagnosis could be made only by an x-ray examination, which would always show such a condition if it ever had been present. I informed the patient that a person can have a definite gallbladder condition without the gallbladder visualization test showing any signs or defects of the gallbladder. Is this statement correct? Also is there very much difference in the diet of a person suffering from a subacute or chronic gallbladder condition from that of a patient with a high blood cholesterol? Sidney Scheinman, M.D., New York.

Answer.—The gallbladder visualization test serves to show whether the gallbladder ducts are patent and will admit the dye. In addition, the dye sometimes supplies a background against which stones that would otherwise be invisible may be seen. Dye will enter a diseased gallbladder. It frequently does so when stones are present and will do so as long as the ducts are not completely obstructed. Whether the concentration of the dye will be as great in diseased gallbladders is a matter of debate. There are, however, other factors that will influence concentration, including an obese abdominal wall that gives an apparent lack of concentration and deficient absorption of the dye. Considering all these things it is quite correct to say that gallbladder disease may exist in the presence of a negative Graham-Cole test. It should be added, however, that this does not happen often.

The statement that x-ray examination would always show such a condition if it ever had been present may be challenged. Work has been published to show that nonvisualizing gallbladders may later visualize well. In one series of published cases the dye was administered orally in all instances. In another series the dye was injected intravenously in all instances. By either technic it was found that positive tests (that is, nonvisualizing gallbladders) later became negative. This improvement was credited to medical management but, whatever the cause, the facts are clear.

The diet for hypercholesteremia is not essentially different from the diet used in gallbladder disease. As a matter of fact, gallbladder disease is one of common causes of hypercholesteremia. However, one should be sure that no other cause for hypercholesteremia exists.

REBOUND TENDERNESS AND ROVSING'S SIGN

To the Editor:—Please discuss the significance of "rebound tenderness" in abdominal disease and the physiologic basis for its production. Is this term synonymous with Rovsing's sign? M.D., Illinois.

Answer.—Rebound tenderness is an important diagnostic finding in the examination of the abdomen and always means involvement of the parietal peritoneum. Whereas tenderness on direct pressure is readily elicited in inflammatory lesions involving the abdominal viscera, the sudden release of the examining hand does not result in pain unless there is involvement of the parietal peritoneum. Unquestionably the physiologic mechanism for the production of pain is that in the presence of inflammatory involvement of the parietal peritoneum the sudden release of pressure will result in movement of the peritoneum and pain, similarly to that which occurs when pain results from movement of the diaphragm if the serosal covering of the diaphragm is inflamed.

Rebound tenderness is not synonymous with Rovsing's sign, which is pain referred to McBurney's point when pressure is exerted on the descending colon. This finding is not infrequently present in chronic appendicitis as well as in acute appendicitis. Presumably the increase in intracolonic pressure produced by compressing the descending colon and its transmission to the lumen of the appendix are responsible for the pain. Rebound tenderness was first described by Blumberg.

EFFECTS OF ANTIPYRETIC DRUGS ON MEASLES ERUPTION

To the Editor:—What is the effect of antipyretic drugs given during the prodromal and preeruptive stages of morbilli? Does the lowering of the temperature tend to prolong the period of eruption? Verna M. Pennington, R.N., Lennox, Calif.

Answer.—Antipyretic drugs administered during the preeruptive stage of measles ordinarily do not affect the duration of eruption. At one time it was reported by some clinicians that the administration of aminopyrine during the prodromal stage of measles modified or shortened the duration of the rash.

VAGINAL DOUCHES

To the Editor:—Included in the answer to a query in *The Journal* Aug. 10, 1946, page 1254 was the statement "for those who insist, douches should be used not oftener than once or twice a week at most." I question the value of douches quite aside from the fact that it requires a lot of work for a busy, tired, half-sick woman to prepare, take, and clean up after a douche. However, specialists in gynecology still prescribe vinegar douches daily for a month or six weeks at a time as an adjunct to the treatment of trichomonas vaginitis. Please discuss the advantages and disadvantages of douches. M.D., Florida.

Answer.—Vaginal douches are a mechanical means of removing discharge and also of reducing odor associated with excessive vaginal discharge. There is little documentary proof that douches per se are especially therapeutic. The contention has existed but has not been completely proved that the vaginal acidity can be reestablished by the use of vinegar (acetic acid), lactic acid and other acids in the daily douche. A disadvantage to douches is that they remove the discharge and secretion and may interfere with the material for satisfactory microscopic examination unless there has been a lapse of a few days since the last irrigation. Some prefer to use a douche solely for cleansing purpose shortly after completion of the menstrual period, and also late in the puerperium to remove lochial discharge. Douches are unreliable for the production of pelvic hyperthermia. Where materials are deposited in the vagina in association with treatment the douche may be employed occasionally to make sure that there is not an excessive accumulation of the therapeutic agents and its vehicle. Many gynecologists avoid the use of douches except for cleansing purposes and astringent values in the treatment of cervicitis. Occasionally a deodorizing agent may be employed to reduce the odor of advanced cervical carcinoma.

PROPHYLACTIC DIGITALIZATION

To the Editor:—Is there any evidence that the administration of digitalis before operation to a compensated heart patient is valuable in preventing the onset of congestive heart failure? The patient in question has never had congestive failure. Does full digitalization of a compensated heart have any value in preventing the onset of heart failure? Harry R. Deane, M.D., Bay Pines, Fla.

Answer.—The term "heart patient" is rather indefinite. The query could be answered more intelligently if the type of heart disease or disorder was known. Generally speaking, the principal indication for the use of digitalis is congestive heart failure. It is surprising how seldom congestive heart failure comes on as the result of a well conducted surgical procedure. Peripheral vascular collapse or the onset of an abnormal rhythm occurs much more commonly in the wake of a surgical operation, and neither of these is benefited by digitalis. Indeed, digitalis is usually contraindicated in such emergencies. Latterly, some evidence has been produced to indicate that digitalis increases the tendency of the blood to clot within the vessels. This is a distinct disadvantage following surgical procedures. There is lack of unanimity of opinion among cardiologists concerning the ability of digitalis to prevent the onset of congestive failure in the compensated heart but, considering the possible disadvantages, it would seem unwise to administer it without a direct indication.

There is a group of "heart patients" in which the prophylactic use of digitalis might be countenanced. These are patients with chronic auricular fibrillation. The heart rate is usually greatly increased in auricular fibrillation following surgical procedures and digitalis control might be of advantage in these cases.

TREATMENT OF EPIDEMIC KERATOCONJUNCTIVITIS

To the Editor:—Please discuss the use of human globulin in the treatment of virus conjunctivitis and superficial punctate keratitis. Harold L. Snow, M.D., San Pedro, Calif.

Answer.—Human plasma has been used in the treatment of epidemic keratoconjunctivitis, which is undoubtedly a virus disease. This disease is associated with a superficial keratitis. The plasma has little or no effect on the superficial keratitis once it has developed, but has a profound beneficial effect on the disease if given early. It is doubtful that human globulin or human plasma would be of much benefit after the disease of the cornea or conjunctiva is well established, since the virus is undoubtedly fixed in the cells and may not be reached by the antiviral bodies. Similar experience has been found with use of human globulin with other types of viral diseases.

PRESENT TRENDS IN THE PRACTICE OF NEUROLOGY

GEORGE WILSON, M.D.
and
CHARLES RUPP Jr., M.D.
Philadelphia

From many quarters there arise diverse voices intimating that in this day and time the clinical neurologist is destined to become merely an anachronism, whose former functions might now better be relegated to other colleagues, especially the psychiatrist and the neurosurgeon. The internist proclaims that to him, rightfully, belong the infections and deficiency, toxic and vascular disorders of the nervous system; the syphilologist requisitions the cases of syphilis of the central nervous system; the pediatrician deems only himself competent to manage the neurologic disorders of childhood, and the allergist disputes for the paroxysmal dysfunctions such as migraine, Ménière's syndrome and cephalalgia. The orthopedist treats both spastic and flaccid paralyses and the neurosurgeon seeks the traumatisms and neoplasms of the nervous system, while the psychiatrists consider only themselves competent to manage the case in which there is the slightest psychogenic component. For the clinical neurologist there remain only the leavings of a few heredodegenerations, an occasional rare disorder of occult causation, poor in prognosis and unamenable to therapy, and possibly a minor role as the penultimate consultant a few hours in advance of the pathologist, at the bedside of a moribund patient whose symptoms still remain a baffling mystery.

Such are the trends of the times, and as auguries of the future one hears of plans in one medical school to reorganize the department of neurology in some obscure and insignificant attic of the department of medicine, in another to reduce the time allotted to clinical neurology to a few didactic lectures in the third year, eliminating entirely any bedside instruction, while more and more hours are devoted to psychiatry, even at the expense of reducing the time formerly devoted to anatomy, chemistry, pathology and bacteriology.

Chief among the Cassandras anticipating the early demise of the clinical neurologist is his colleague, the so-called "pure" psychiatrist, who, though intoxicated with grandiose dreams about curing all the political, marital, martial, racial and economic ills of a sorely troubled world by the application of psychiatric principles, is still unable to maintain a tolerable harmony amidst his own ranks. So preoccupied have some psychiatrists become with the broader sociologic, political and even mystic attributes of their specialty that they would divorce themselves entirely from any allegiance to medicine. We have heard one eminent psychiatrist state, in all seriousness, that he considered it a grievous detriment that the psychiatrist is compelled to study medicine at all, since it prejudices in favor of the structural and "organic." In his opinion, a far better training might be oriented in the disciplines of sociology, anthropology, economics, history, psychology and psychoanalysis. Another equally eminent psychiatrist of our acquaintance boasts that he never performs a physical examination lest the patient gain the misapprehension that something amiss with his body might be responsible for his symptoms. Evidence that these opinions are not isolated idiosyncrasies is to be found in the agitation on the part of many psychiatrists that it is unfair to demand even the most elementary knowledge of clinical neurology and its related basic sciences of their younger disciples, who are seeking certification as specialists; they see nothing incongruous in a psychiatrist so neurologically naive that he considers the red nucleus some mysterious appendage of the U. S. S. R. How ridiculous all this must seem when approximately 51 per cent of the patients confined in mental hospitals in the United States suffer with a form of psychosis directly attributable to disease of the nervous system or some other organ of the body![1]

We do not hesitate to confess that in our personal experience as practicing neurologists, who, if we may be permitted to say so, have had considerable training in psychiatry, we frequently find it difficult to assess whether a patient's symptoms represent manifestations of a structural disease of the nervous syestem or whether they should be regarded as being emotionally or psychogenically conditioned, and we are compelled to utilize to the utmost as much knowledge of internal medicine, neurology, and psychiatry as we possess. In a previous paper[2] we have called attention to the fact that diverse diseases of the central nervous system such as chronic encephalitis with parkinsonism, multiple sclerosis, pseudosclerosis, dystonia musculorum deformans and tumor of the brain, may first become manifest in a setting strongly colored by emotional and psychic turmoil, and the correct diagnosis is often extremely

difficult. More recently, we have reported[3] a series of cases of tumors in the posterior fossa of the brain in which mental symptoms were often the presenting complaint. Daily in our practice we encounter cases in which neurologic, psychiatric and internal medicine components are inseparably intermingled, cases which cannot be adequately managed by a practitioner whose orientation is exclusively psychologic. We cite briefly 3 cases:

REPORT OF CASES

CASE 1.—A white married housewife, aged 45, complained of fatigue and progressive loss of appetite of one month's duration. A week later a dull aching midabdominal pain developed, accompanied by spells of hiccuping and vomiting. Her bowels, formerly always regular, became constipated, and she lost 15 pounds (6.8 Kg.) in weight. Physical and neurologic examination revealed nothing of significance aside from evidence of loss of weight and a slight diffuse enlargement of the thyroid gland. Examination of the blood revealed hypochromic anemia, with 12.2 Gm. of hemoglobin per hundred cubic centimeters and a red blood cell count of 3,240,000. Results of other laboratory studies including estimations of sugar and urea in the blood, tests of the blood serum, urinalysis and determination of the basal metabolic rate, were within normal limits. Complete roentgenologic examination of the gastrointestinal tract revealed only hyperperistalsis. She was seen by two internists, as well as by her family physician, all of whom agreed that there was no organic basis for her symptoms, which were considered to be psychogenic in origin since she had always been a worrisome, perfectionistic type of person, and recently had been disturbed by her husband's interest in a younger woman. She was referred to a psychiatrist for psychotherapy. In spite of this, her vomiting and hiccuping continued, and intravenous infusions became necessary. Four weeks after the onset of her symptoms, while in the midst of a stormy visit from her husband, there suddenly developed a left-sided jacksonian seizure, which was followed by a generalized grand mal attack. Similar jacksonian attacks, alternately involving both sides, and grand mal convulsions continued at three to five minute intervals, persisting in spite of all therapy. In the intervals between attacks the neurologic examination disclosed no abnormality and examination of the fundi revealed no choking. The roentgenogram of the skull was likewise normal. Chemical studies of the blood after the onset of the convulsions revealed 18.4 mg. of calcium per hundred cubic centimeters of blood. The patient alternated between deep coma and continuous convulsions for six days. The temperature gradually rose to 106 F. Three subsequent determinations of calcium in the blood revealed levels of 21.3, 24 and 26 mg. per hundred cubic centimeters. There was 3 mg. of phosphorus per hundred cubic centimeters of blood, and there were 4.1 units of phosphatase activity. Roentgenograms of the spine and of all long bones revealed only a slight general decalcification, which was not considered clinically significant. Operation was considered inadvisable by the consulting surgeon on account of the patient's poor condition. At necropsy, the chief finding of interest was a cystic adenoma of the parathyroid gland.

CASE 2.—A white girl, a college student aged 17, was admitted in a state of agitation, complaining of "terrible nerves." Three months before she had made homosexual advances to a classmate, but was spurned. Thereafter she became dissatisfied with her classes and fellow students, took a dislike to her food, began vomiting and felt tired. Two weeks before admission she caught a "very bad cold," but after a week recovered. She returned to her classes but felt too weak to walk. She was unable to sleep, became agitated, had difficulty in breathing and complained of pains in the stomach, the nose and sinuses and the lower part of the chest. At the time of physical examination, the patient was agitated, grunting and moaning with each respiratory effort. She claimed that she could not lie down to cooperate with the making of the examination because of inability to breathe, but cooperated well when a woman resident physician made the examination. Physical examination revealed nothing significant aside from labored respirations of 30 per minute and a pulse rate of 130. Although she claimed that she could not walk, neurologic examination revealed nothing significant. A diagnosis of hysteria was considered. In an attempt to quiet her agitations and to obtain rapport, the patient was given 0.8 Gm. of sodium amytal intravenously and questioned regarding her conflicts. After twenty minutes of the narcoanalytic interview she became increasingly resistive, agitated and assaultive. An attempt was made to give more sodium amytal. The patient suddenly ceased breathing, and artificial respiration was of no avail. At necropsy, the only finding of significance was a large firm yellow tumor, weighing 1,530 Gm., which filled the entire mediastinum, extending up into the neck and compressing the heart, the lungs and the aorta. Histologic examination revealed the tumor to be a thymoma.

CASE 3.—A white stenographer, aged 20, was operated on for acute appendicitis. Her convalescence was uneventful until the fourth postoperative day, when she suddenly became mute, negativistic and resistive and showed cataleptic rigidity. From information obtained from her family, it seemed reasonable to assume that her personality make-up was fairly stable, and she had made an excellent previous adjustment to her school work and occupation. It was noted that for about a week previous to her operation she had vomited frequently and eaten little. Since the operation she had had nothing by mouth except water. A chemical examination of the blood was suggested, and it was found that there was only 40 mg. of sugar per hundred cubic centimeters of blood. Her symptoms promptly disappeared after the intravenous administration of 50 cc. of a 50 per cent solution of dextrose, and she has remained well over a period of five years since, making a satisfactory adjustment.

Undoubtedly some critics will insist that cases similar to the foregoing are the proper province of the psychosomaticist. Originally motivated by the intention of stressing the interdependence of body and psyche, it appears that, save for a few isolated exceptions, most of the psychosomaticists have become too preoccupied with the aspects of the psyche, to the neglect of the soma. The direction of the bias is indicated by the fact that most training programs in psychosomatic medicine insist on a personal psychoanalysis. To neurologists, much of the psychosomatic literature with its attempts to blame many, if not all, the diseases which afflict humanity on too rigid personalities, beset by frustrations and emotional conflicts, falls into the fallacy of "post hoc, propter hoc" illogicality and is unconvincing. Perhaps the harvest might be more fruitful if more time were expended on a study of the effect of the soma on the psyche rather than the converse. We have in mind further investigations, such as those of Saphir[4] on the relationship of hypochloremia to psychoneurotic states, of Miller[5] on the effects of lowering the intake of salt in relation to insomnia and tension, investigations of such problems as suggested by Benjamin and Hoyt,[6] who found both psychoneurotic and parkinsonian-like syndromes as residual disabilities of hepatic damage suffered incidental to postvaccinal hepatitis, and studies such as those of Karlan and Cohn[7] on the relationship of hypoglycemia to fatigue. Further evidence of the importance of somatic factors in mental disorders are revealed by the studies of Riggs[8] from the Neuropathologic Laboratory of the

Philadelphia General Hospital. In 121 cases in which the patients died during an acute psychotic episode, the following visceral disease was noted:

Cardiovascular disease		61 cases
Cardiovascular renal	27	
Syphilitic	15	
Peripheral circulatory failure	12	
Rheumatic endocarditis	7	
Metabolic disorders		39 cases
Chronic alcoholism	13	
Nutritional deficiencies	10	
Plumbism	2	
Hyperthyroidism	2	
Fatty degeneration of the liver (cause unknown)	12	
Cerebral neoplasm and trauma		12 cases
Anemias and infections		9 cases

One hundred and twelve cases (93 per cent) in addition presented congenital anomalies of the vascular tree, consisting of anomalies of the circle of Willis and hypoplasia of the heart and the aorta, either associated or singly. In the presence of such congenitally inadequate circulation, one may speculate that even slight biochemical disturbances occasioned by mild somatic disease might produce sufficient anoxia to initiate disturbances of cerebral metabolism which could become clinically manifest as mental disorders.

Regardless of whether the cause of the so-called functional psychoses ultimately proves to be neuronogenically or psychogenically determined, the psychiatrist can no more hope to comprehend the problems of his present day patients, if he is devoid of any knowledge of clinical neurology than can the neurologist attempt to treat even the simplest case of paralysis without some knowledge of the structure and functions of the personality. If the neurologist can acquire a respectable mastery of the fundamentals of psychiatry, is it beyond the capability of the psychiatrist to possess an equivalent knowledge of the basic anatomy, physiology, pathology and clinical disturbances of the nervous system?

While both neurology and psychiatry owe much to, and must ever rest (as must every specialty) on a firm grounding of internal medicine, it is deplorable to contemplate that the management of disorders of the nervous system should be relegated to the internist or his colleagues in the subspecialties of allergy, syphilology and pediatrics. It is to be remembered that the reactions of the nervous system which manifest themselves as symptoms are rather limited and are common to many diverse etiologic agents. It is unfair to place the responsibility for determining whether a convulsion is the expression of an underlying tumor, trauma, infection, vascular disturbance, degeneration, metabolic disorder or psychic conflict, on one whose orientation is mainly extraneural and whose knowledge of the structure, function and pathology of the nervous system is represented, with rare exceptions, by hazy memories retained for the most part from the first two years of medical instruction. Nor is the neurosurgeon inevitably predestined to be chief in the management of the neurologic cases. While in some cases his aid is indispensable, it is to be remembered that in a large general neurologic service, such as that at the Philadelphia General Hospital, where both neoplastic and traumatic cases are assigned, less than 2 per cent of all patients with neurologic disease require treatment by neurosurgical methods. In most instances, the training of the neurosurgeon has been mainly along surgical lines, the technical intricacies of his art consume much of his time and, with few exceptions, the neurosurgeon does not pretend to proficiency in neurologic diagnosis.

In the warfare against the ravages of disease of the nervous system, there is no place for internecine strife and bickering as to what is purely neurologic or purely psychiatric or purely neurosurgical. There can be no arbitrary division of the disorders of the nervous system into isolated compartments, each managed by an isolated specialist. Future progress requires the coordinated team work of the clinical neurologist, the psychiatrist, the internist and the neurosurgeon, mutually strengthened by the assistance of the neuroanatomist, the neurophysiologist, the neuropathologist, the biochemist and workers in the other basic medical sciences. Without a thorough foundation in the essential principles of neurology, anatomy, physiology and internal medicine, psychiatry becomes as sounding brass and a tinkling cymbal, full of sound and fury, signifying nothing. Let the psychiatrist postpone his gratuitous advice regarding the cures of the ills of the body politic until such time as he has more effectively mastered the causes and treatment of the mental ills of the individual patient. Let him abandon the hustings and return once more to the clinic and the laboratory. Those who consider psychiatry a discipline apart might well heed the warnings of S. Weir Mitchell,[9] which, although uttered over fifty years ago at the fiftieth meeting of what is now the American Psychiatric Association, are still pertinent:

> . . . that which is impairing the usefulness of the lesser specialties in medicine has been more grossly enfeebling your value and retarding your development. I mean the tendency to isolation from the mass of the active profession . . . you were the first of the specialists, and you have never come back into line . . . you soon began to live apart, and you still do so. . . . You live out of range of critical shot. . . . Nor can I cease to lament the day when the treatment of the insane passed too completely out of the hands of the profession at large, and into those of a group of physicians who constitute almost a sect apart from our vitalized existence.

Likewise pertinent are the words of Bernard Sachs,[10] uttered in 1897 before the same society:

> Far from being foes or even antagonists, we are struggling for a common cause, and should be united against the common enemy, . . . the diseases of the nervous system. Do what we will, we cannot separate diseases of the mind from the organic diseases of the brain and spinal cord. No one can be thoroughly devoted to a study of the latter class without at the same time taking a deep interest in psychiatry. I have no doubt that others like myself would never have entered the ranks of the neurologists if they had not been impelled to the study of nervous affections by a special fondness for the analysis of mental conditions. . . . Mental diseases should be studied not only with reference to the needs of society . . . but the relations of insanity to the entire organism, its relation to other acute and chronic nervous diseases.

In the years elapsing since Mitchell and Sachs spoke so wisely, the psychiatrist has emerged from the isolation of the asylum and now frequents the general wards and consulting room, but many of the evils of immurement linger. The isolation in viewpoint persists, and too often the psychiatrist considers himself apart from his fellow practitioners. Persistence in this attitude can lead only to cultism. Further progress in solving the still vast problems of causation and therapy of mental disorders will be delayed until the psychiatrist becomes truly a physician, well versed in all disciplines relevant to the structure and functioning, in health and disease, of the most complex organ of the body, the nervous system.

ABSTRACT OF DISCUSSION

Dr. J. M. Nielsen, Los Angeles: I want to point out that clinical neurology is only staggering a little; it is not going down. Let us see what has happened in psychiatry in the last few decades. Every advance in psychiatry that has been made in the last few decades has been made on the basis that the mind resides in the brain. Insulin shock replaced the former psychotherapy of dementia praecox. Metrazol and then electric shock came along and have even surpassed insulin shock in therapeutic results. These methods of shock therapy do not shock the patient into a willingness to get well; they make him well in spite of himself by correcting to a large extent the abnormal condition that exists in the brain. The brain is the organ of the mind. Every thought, every idea of any sort, every hallucination, every delusion has a neural basis. There cannot be a thought without its traveling over the neurons of the brain.

There are many things which we neurologists do not know. We do not have any idea or misconception that there is a certain focus in the brain in which a lesion will produce a psychoneurosis. We do not believe that that can ever happen. We believe that a psychoneurosis results from a poor use of normal structure. We do not want to pretend to know anything which we do not know, and all that we want to do is to extend gradually, perhaps slowly. But we believe that certainly within another half century psychiatry will be well understood on the basis of neurology.

With regard to the neurologic surgeon and clinical neurology, there is a certain temperamental difference between a surgeon and a clinical neurologist. A surgeon wants action, and he wants it in a hurry. He wants to remove that lesion and have the patient well. He is not much of a philosopher as a rule. The neurologist has the philosophic attitude of the psychiatrist and the technical leaning of a neurosurgeon, and that is where he comes in. He is willing to spend months, if necessary, in examining and reexamining the case and deciding whether surgical intervention is needed. I think that there will be a constant, good liaison between the neurosurgeon and the neurologist simply because they are necessary to each other.

Dr. John B. Doyle, Los Angeles: It is greatly to the credit of Dr. Wilson and Dr. Rupp that they have brought into the open discussion of a problem of such fundamental importance. Society at large and the medical profession in particular have for several generations been threatened by the development of a dichotomy between those interested in the total expression of the nervous system of man and lower animals and those interested solely in psychiatric norms and deviations. The problem has been complicated during the twentieth century by the evolution of neurosurgery and, to a lesser degree, by the changing purviews of the internist, the pediatrician, the syphilologist and the allergist. In my opinion the situation which confronts those of us who are interested in the nervous system as a whole, in the advancement of knowledge and in the elevation of standards of practice in neurology and psychiatry is not one which should put us on the defensive or lead to acrimonious generalizations or ultimatums. The logical approach to anything like a satisfactory resolution of the evils that have arisen, and the greater ones that hover in the future, is through a program of education of the people as a whole and of administrators of the medical services of the army, navy and public health, of hospitals and of medical schools. Such a campaign may at first glance appear grandiose and impractical. Yet it is the means by which the more vocal portion of our specialty has advanced itself to a point where it threatens the extinction of progress in neuroanatomy, neurophysiology, neuropathology and clinical neurology, the sciences from which psychiatry has derived its essential substance.

Dr. Walter F. Schaller, San Francisco: I practice neurology by choice, but psychiatry by necessity—not exactly financial necessity but the necessity of keeping busy because of the inclusion of clinical neurology in so many other specialties and the close relationship between neurology and psychiatry. It is apparent from the report of Dr. Rupp that the psychiatrist often lacks a sufficient foundation in neurology or has forgotten what he has learned about neurology. Assuming that the latter is true, perhaps the explanation is not too difficult because of the wide field that psychiatry is now attempting to cover. For example, I have had requests to examine patients who wished consultations for the following reasons: household dissensions, maladjustments in marriage, unrequited love, draft evasion, because they were dissatisfied pensioners and because they wished to evade the penalties of the law. I often advise these patients to consult their parents, their religious adviser, their lawyer or, as an alternative, to go to an analyst. Is it, then, any wonder that many psychiatrists cannot keep pace with scientific advances in neurology and psychiatry? I have looked up the definition of "neurology" in Webster and found that it is defined as "that branch of science which treats of the nervous system." Unless psychiatrists object to this definition, they must admit that their specialty is but a part of neurology. I will conclude by quoting a paragraph of Dr. Pearce Bailey's paper read before the American Neurological Association last week. It is so conservative and so nicely worded that I am sure that those of you who heard it will be pleased to hear it again. "I do not believe that the existing predominance of a psychological orientation constitutes a valid cause for alarm to clinical neurologists. After all, the psychological approach represents only a particular method or technic for the investigation of the disorganized nervous economy. It cannot presume to rise above the constellation of physiological and social forces of which it is a part, any more than water can be expected to rise above its source."

Dr. Roland P. Mackay, Chicago: Lest it be thought that this is merely a session of breast beating on the part of neurologists, I should like to emphasize two points. The neurologist himself is often to blame for the difficult situation in which he finds himself. Many neurologists have so divorced themselves from the knowledge of medicine and surgery in general that they are placed by their confreres in the class of partial physicians. Perhaps that condition arose from the fact that neurologists originally were closely associated with state hospitals and lived in an ivory tower, far from the practice of medicine. A good neurologist is one who knows general medicine, because the majority of symptoms which come under his purview have their origin in general medical conditions. If the neurologist wants to endear himself to the heart of the internist, he will have to know more about general medicine and so make his specialty applicable in the mind of the internist. My second point is that the neurologist's difficult situation is in no small part due to the referring physician, sometimes the ophthalmologist. Because of the unpretentious role of medical neurology and the brilliance of neurosurgery since Horsley, because the sunlight of popular attention glitters on the silver scalpel in the surgeon's hands and because neurosurgery naturally deals with organic conditions, the average physician has come to identify organic neurology with neurosurgery and, contrariwise, to identify the neurologist with the functional or psychogenic disorders. It is not necessary to send every patient with a homonymous field defect to a neurosurgeon. Perhaps the majority of patients who have field defects should go to a medical neurologist rather than to a neurosurgeon. It is not necessary to send every patient who limps or has some motor difficulty to a neurosurgeon. In fact, the neurosurgeon, because of his diagnostic limitations and because his attention is directed primarily to surgical conditions, is not able to make a correct and thoroughgoing appraisal of such cases. The fault is the neurologist's in not keeping his mind open to the whole broad field of medicine, and, secondly, it is the fault of the referring physician, because he identifies organic conditions with surgery. Both of these mistakes can be rectified easily, and perhaps the future of neurology will be much brighter than the Cassandras think.

Dr. Henry R. Viets, Boston: I should agree that neurology is at a low ebb, but as I see the subject, the tide is turning and turning rapidly. Witness the extraordinary enthusiasm of the meeting last week in San Francisco of the American Neurological Association under Dr. Schaller, the establishment of a strong neurologic department in the University of California Medical School under Dr. Aring, and the fact that we are discussing this very problem here at the meeting of the American Medical Association. Neurology can be advanced only by neurologists. The minute a department in a medical school or even in a hospital is abandoned, as has unfortunately occurred in this country, neurology falls to a low level as far as the advancement of our knowledge of nervous diseases is concerned. In a medical school perhaps our primary duty is to train medical students, and we must realize that a sound training in neurology is essential for the practice of general medicine, which after all is what 85 per cent of our students are going to do. Osler used to say that 15 to 20 per cent of his diagnostic problems in consultations were neurologic in character, and 50 per cent of his early papers were written on neurologic subjects. He, like every outstanding internist, was a good neurologist, but the exceptions are many and the average internist or specialist in other fields of medicine cannot be a good neurologist. Only the neurologist can be a good neurologist, and only the neurologist will advance the knowledge of diseases of the nervous system.

EARLY RECOGNITION AND MANAGEMENT OF INTESTINAL STRANGULATION

EVERETT IDRIS EVANS, Ph.D., M.D.
and
I. A. BIGGER, M.D.
Department of Surgery, Medical College of Virginia
Richmond, Va.

Although improvements in therapy have resulted in a decided reduction in mortality in simple mechanical obstruction of the small bowel, the mortality in strangulation obstruction is still high. In a recent report by McKittrick and Sarris,[1] 59 per cent of the deaths in their patients with intestinal obstruction occurred in the strangulation group. In the hospitals of the Medical College of Virginia, strangulation of the small bowel has been responsible for more deaths in the years 1941 to 1946 than appendicitis with rupture and peritonitis.

Most authors agree that the most important factor influencing a favorable outcome in strangulation of the small bowel is early surgical intervention. A study of the patients seen by us during the past five years has impressed us with the likelihood that if close attention is paid to the clinical history and to the physical observations early and correct diagnosis of intestinal strangulation is usually possible. In this communication, therefore, we describe the clinical observations which we consider important in distinguishing between mechanical obstruction and strangulating obstruction of the small bowel.

THE DIFFERENTIATION OF SIMPLE VERSUS STRANGULATION OBSTRUCTION

In the following discussion we have assumed that the physician, after a careful history and physical examination, has concluded that of the abdominal disorders which might be responsible for the condition of the patient mechanical obstruction of the bowel is the most likely. *Briefly stated, the immediate question then is, "Does this patient have a simple or a strangulating obstruction?"*

In this review of our experience, we have excluded all cases of strangulation of the small bowel incident to external hernia; 2 cases of strangulation due to intussusception are excluded because the diagnosis was so obvious at the first examination.

SYMPTOMS

Pain.—*Pain is the commonest symptom in obstruction of the small bowel.* Although it is generally stated that in both types of obstruction the onset is sudden, we are impressed by the dramatic onset of pain in strangulating obstruction; it is likely to be sudden and severe, even violent. In this respect the patient with strangulation resembles those of other clinical states where the flow of blood to a part is suddenly obstructed (coronary occlusion or embolus to a main artery of any extremity). In simple obstruction the patient may recall that in the earliest hours there had been abrupt, periodic increase and cessation of the pain, but in strangulation the pain is generally continuous without intervals of complete freedom from pain.

Vomiting.—Practically all patients with mechanical obstruction of the small bowel vomit. However, in our series, we are impressed with the incidence of frequent, *repeated vomiting by the patients with strangulating obstruction.*

THE PHYSICAL EXAMINATION

General Physical Observations.—The patient with strangulating obstruction usually appears extremely ill, while the majority of patients with simple obstruction do not appear particularly ill except, perhaps, during periods of severe cramping pain or late in the disease.

Shock.—If the clinical signs of shock (blood pressure low or falling; rapid weak pulse; peripheral cyanosis; cold sweating extremities; patchy cyanosis of the chest or abdomen) appear in a patient with small bowel obstruction after only a few hours, the obstruction is almost certainly strangulating. Unfortunately, the clinical evidences of shock are usually not observed until the blood volume is reduced by at least 25 per cent.[2] Shock is seen too late in strangulation to be of help in differentiating it from other types of bowel obstruction.

THE SIGN OF "POSITION OF RELIEF"

We have observed that the patient with volvulus usually assumes a particular position in the bed, in which position they state they are freer of pain than in other positions. It is probable that this "position of relief" reduces traction on the mesentery, thus giving partial relief from the constant pain. We have therefore designated this position the "position of relief." As far as we are aware *this sign has not previously been* described in connection with the differentiation of strangulation, especially volvulus, from other forms of obstruction (see the accompanying illustration).

This "position of relief" has been seen only in obstruction due to strangulation of the bowel. It was noted in all but 2 of our patients in the strangulation group. Practically all patients with simple obstruction of the small bowel appear to be comfortable in the supine position and do not complain when they are moved from this position. Patients with strangulation obstruction generally lie in a "position of relief." This position may be on one or the other side. One patient (W. B.) experienced some relief only while sitting upright, inclining forward. If patients with a strangulation obstruction are moved from the "position of relief" they complain more severely of their abdominal

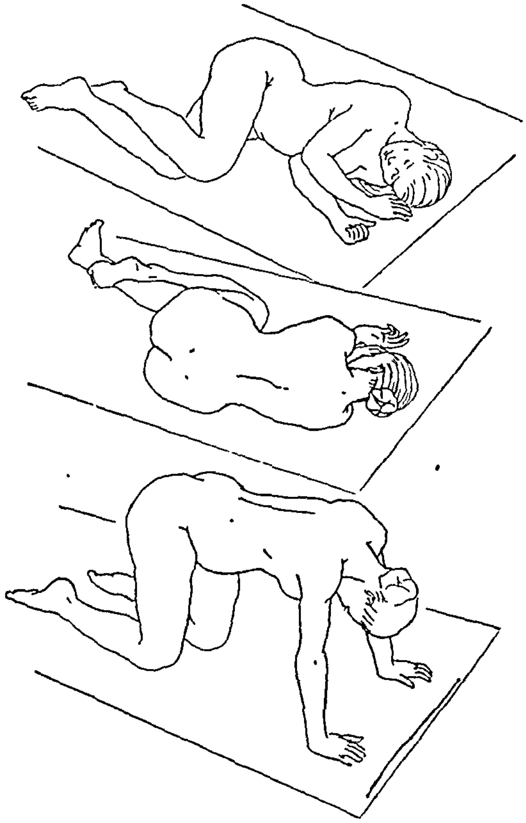
pain. It is a simple matter during the course of an abdominal examination of a patient suspected of strangulation of the small bowel to have the patient assume the position most comfortable for him and then to move him into other positions and ascertain if there is accentuation of the pain in these other positions.

If the patient states he is only relatively free of pain in one certain position (the position he will assume for relief) we believe this fact is highly suggestive of strangulation of the bowel.

As noted by McKittrick,[3] some patients with strangulation complain of pain in the back. In those who show a positive sign of "position of relief" there is apt to be an increase in dorsal pain when they are shifted into other positions.



The "position of relief" usually to be found in patients with strangulating volvulus. Upper and middle, the positions usually assumed as the "position of relief", i. e., on either right or left side with legs slightly drawn up. Lower, the knee-chest position was seen as the "position of relief" in 1 patient with a strangulated loop of intestine.

THE ABDOMINAL EXAMINATION IN OBSTRUCTION OF THE SMALL BOWEL

Probably in no other clinical situation is a careful physical examination so important as when the physician must decide whether a patient has simple or strangulating obstruction of the small bowel. Only after assembling information gained by inspection, palpation, percussion and auscultation of the abdomen can one properly decide which type of obstruction is present, but we believe, as does Wangensteen,[4] that the experienced observer can distinguish between simple mechanical obstruction and that of strangulation in which the blood supply to the obstructing loop is impaired.

Inspection.—We have not found any significant difference in the general appearance of the abdomen in the two types of obstruction. In 10 of our 14 patients with strangulation there was obvious distention of the abdomen, but distention is often seen in patients with simple obstruction. We do not consider this observation helpful.

In most cases of intestinal strangulation the patients, when seen early, do not have sufficient splinting of the abdominal muscles to interfere with respiratory movements.

Palpation.—As Wangensteen [1] has pointed out, when the venous flow to a portion of the obstructed bowel is interfered with "the gut becomes infarcted and a serosanguineous fluid escapes into the peritoneum causing the latter to become sensitive." Abdominal tenderness is therefore present in most patients with strangulation. In fact, tenderness was present in all 15 patients of our group, and in some the tenderness was associated with local or generalized muscular spasm. Rebound tenderness was elicited in certain patients with intestinal strangulation. In 4 patients a mass was palpated.

Such tenderness is not found in simple obstruction of the bowel. Tenderness and muscular spasm usually mean strangulation. The finding of a palpable mass adds further support to this diagnosis.

Rectal and vaginal examinations should be made in all patients with intestinal obstruction because these examinations sometimes give valuable information. In 2 of our cases of strangulation the abdominal mass could only be palpated by rectal or vaginal examination.

Auscultation.—If the physician will auscultate carefully all patients with intestinal colic we believe he will, with the experience thus gained, be able to distinguish between the sounds heard in simple and strangulation obstruction. Prolonged observation is often necessary.

It is difficult to describe the difference between the sounds heard with the two types of obstruction. Early in strangulation sounds may still be present, but we believe that they are (1) heard less frequently and (2) are of somewhat lower tone and pitch than in simple obstruction. The intervals between sounds may be relatively long (up to ten or fifteen minutes), and the duration is usually quite short. As time goes on the intervals of silence lengthen, until finally sounds no longer are heard. Occasionally the abdomen may seem silent even when auscultated early in strangulation. The examiner should then resort to longer periods of auscultation, even up to ten or fifteen minutes. When the other observations point to mechanical intestinal obstruction infrequent, low pitched sounds strongly suggest strangulation.

Percussion.—The observations by percussion are not of significant difference in simple and strangulating obstruction until too late to affect the final outcome. Patients with late intestinal strangulation show free fluid in the peritoneal cavity.

LABORATORY DATA

We agree with McKittrick and Sarris [1] that ordinarily the leukocyte count is not helpful in differentiating simple and strangulation obstruction. We consider their view that a rising leukocyte count is suggestive of intestinal strangulation to be sound. If the patient is seen early in the course of the attack, one will generally find a higher leukocyte count in strangulating than in simple obstruction. A pulse rate above 100 in the early hours generally indicates intestinal strangulation rather than simple obstruction, but a review of our own cases of strangulation shows that the pulse rate was below 100 in 6 cases. Since 5 of the 6 terminated fatally, it would appear that the pulse rate is not an especially helpful diagnostic or prognostic sign.

[4] Wangensteen, O. H.: Intestinal Obstructions, ed. 2, Springfield, Ill., Charles C Thomas, Publisher, 1942.

Roentgen ray examination is important in establishing the diagnosis of obstruction of the small bowel but does not appear to be especially helpful in differentiating between simple and strangulating obstruction. The roentgenologic observations were indicative of small bowel obstruction in all our strangulated cases, in 1 as early as four hours after the onset of pain.

TABLE 1.—*Data on Clinical Cases*

Name	Age	Previous Surgical Operation	Type of Obstructing Mechanism	Type of Operation	Cause of Death	Post-operative Survival	Duration of Obstruction
J. T.	7	No	Volvulus of ileum, adhesions	Resection, end to end anastomosis	Survived	....	?
V. F.	21	No	Volvulus of ileum (band)	Exteriorization; 1st stage Mikulicz	Peritonitis	24 hrs.	4 days
M. C.	55	Yes	Volvulus of ileum, cecum and ascending colon	Exploratory laparotomy	Peritonitis	36 hrs.	4 hrs.
F. B.*	78	Yes	Volvulus of ileum	Reduction of volvulus; resection not necessary	Shock	26 hrs.	10 hrs.
J. D.	49	No	Volvulus of ileum (band)	Resection, end to end anastomosis	Anuria (late)	7 days	16 hrs.
J. B.	3	No	Volvulus of ileum (band)	Reduction of volvulus; resection not necessary	Shock (?)	4 hrs.	24 hrs.
C. W.	18	No	Volvulus of ileum (band)	Reduction of volvulus; resection not necessary	Survived	....	4-6 hrs.
M. K.	3	No	Volvulus of ileum (Meckel's)	Reduction and resection of Meckel's diverticulum	Survived	....	8 hrs.
S. B.	46	Yes	Volvulus of ileum (band)	Reduction; resection not necessary	Survived	....	5 hrs.

I. S.	Abrupt perirectal pain	No	No	80	No	Infrequent and low pitched sounds	Exquisite generalized tenderness; mass by rectum	Yes	12,250	6

THE MANAGEMENT OF INTESTINAL STRANGULATION

All patients with intestinal strangulatioin are apt to develop clinical shock. We believe that shock in this group is a result of serious reduction in the volume of circulating blood. Transfusion of whole blood is therefore mandatory before and during surgical intervention. There is evidence that from 1,500 to 2,000 cc. of whole blood will be required to restore to normal the blood volume in this group of patients. (See table 1, patients F. B., L. H. and E. J., for actual depletion of blood volume as shown by measurements with the dye method.)

The restoration of blood volume should be rapid. While the blood is being administered a Levine tube is inserted and the stomach emptied by suction drainage. If there is clinical evidence of dehydration, isotonic solution of sodium chloride may be administered during this period.

Surgical operation should be delayed only for the proper treatment of shock, as delay beyond four to six hours after the onset of intestinal strangulation invites disaster. Strangulation experiments in the dog indicate that as early as four hours after the establishment of strangulation, as much as a 25 per cent loss of blood may occur. Speed in bringing the patient to operation is therefore imperative.

Our choice of anesthesia in patients not in shock is endotracheal ether combined with intercostal block. For patients in shock, we find intercostal block anesthesia with local infiltration combined with small doses of intravenous pentothal sodium useful and relatively safe. In our experience spinal anesthesia is especially hazardous in patients with strangulating obstruction. In an earlier survey [2] in this hospital, 1 patient with volvulus promptly succumbed after the administration of 100 mg. of procaine hydrochloride intrathecally. Another patient (W. B.) died of shock on the operating table even though only local infiltration and intercostal block anesthesia was used.

Table 3.—*Differential Criteria in Simple and Strangulation Obstruction*

	Simple	Strangulation
Pain	Onset may be insidious, may be abrupt	Onset likely to be sudden and severe
	Periods of relief from pain	Pain apt to be constant with intermittent exacerbations
Vomiting	Practically always present	Always present but tends to occur at more frequent intervals in early hours
Appearance of patient	Generally not very ill in early hours; pain only during periods of colic	Generally appears more ill during early hours; more or less constant pain
Position of relief	Practically never seen	Usually seen in volvulus
Inspection	Early distention seen in both types	Early distention seen in both types
Palpation	Tenderness, local and general, not seen early	Tenderness, local and generalized, sometimes associated with rigidity, seen early
	No masses	Mass (tender) commonly palpated
Auscultation	Synchronous concurrence at periodic intervals of pain and metallic or bubbling sounds	Abdomen may early be "silent" If sounds are present, generally of low pitch and infrequent
Laboratory	White blood cell count not helpful	White blood cell counts, on repeated examination, may increase
	Roentgen ray indicates only obstruction	Roentgen ray indicates only obstruction, not strangulation
Shock	Not seen early in simple obstruction	Sometimes seen early (4-6 hrs.) in some strangulation

After the strangulated loop has been isolated from the rest of the abdominal contents, care must be exercised to determine whether or not it is viable. Should resection be required, anastomosis may be performed either by the closed or open method.

A word might be in order about the significance of hemorrhagic peritoneal fluid. We agree with Wangensteen [4] that it "is observed so rarely in simple obstruction that its mere presence is indicative that search should be made for strangulated bowel." In 1 of our cases (M. K.), the strangulated loop might easily have been missed if a diligent search had not been carried out because of the presence of slight hemorrhagic fluid. One patient in this series had been operated on in another hospital, where a normal appendix had been removed in spite of the presence of hemorrhagic fluid. Some hours later he was referred to Dr. Herbert Lee, who found a loop of strangulated bowel.

THE LETHAL FACTORS IN INTESTINAL STRANGULATION

Of all the factors responsible for the fatal outcome in intestinal strangulation, shock and peritonitis are certainly the most important. It will be seen from table 1 that none of the 8 patients who showed signs of clinical shock when first seen recovered from the surgical procedure even though in 2 cases the operation was performed within approximately six hours after the onset of symptoms. One patient (F. B.) survived the surgical intervention but succumbed to one of the sequels of shock—late anuria (seventh day).

When intestinal strangulation is complete and the surgical operation is delayed many hours, if the patient does not die from shock the chance of peritonitis is considerable.

Shock and peritonitis in acute strangulation of the small bowel are usually due, in the final analysis, to avoidable delay in surgical intervention. Early diagnosis is the responsibility of the medical practitioner as well as the surgeon. When as much attention is given to the problem of strangulation of the bowel as has been devoted to acute appendicitis diagnosis will be made earlier and the mortality will decrease.

In the event early differentiation of simple and strangulation obstruction of the bowel cannot be made the recommendation and treatment outlined by McKittrick and Sarris [1] should be followed; i. e., surgical operation on all patients with obstruction examined within twenty-four hours of onset of symptoms. If this is done, relatively few cases of strangulation will be missed. If a patient has had true strangulation of the small bowel for more than twenty-four hours the lethal factors operate with such devastating finality that there is little chance of successful outcome even with prompt surgical intervention.

CONCLUSION

If the character of onset of the attack, the severity and constancy of pain, the presence of tenderness and/or spasm, the character of intestinal sounds and the position assumed by the patient are carefully considered, the differential diagnosis of strangulating and simple obstruction of the small bowel can be made early. Early diagnosis and early surgical operation are essential if the present high mortality of strangulation of the small bowel is to be reduced to a reasonable level.

ABSTRACT OF DISCUSSION

Dr. Leland S. McKittrick, Boston: The diagnosis of acute small bowel obstruction in its early stages is probably one of the really difficult diagnoses to make and one which is missed early about as often as that in any condition that is seen. Dr. Evans stressed the importance of early diagnosis. You and I, who do not see quite as many of these patients as Dr. Evans does, are not going to be too smart in making an accurate differential diagnosis in the early stages of obstruction. Therefore, if we can make a diagnosis of acute obstruction of the small bowel in the first twenty-four hours of the disease then that patient should promptly be operated on with the expectation that he will do well whether he has a simple or a strangulation obstruction.

In our cases at the Massachusetts General Hospital patients who were operated on within eighteen to twenty-four hours of the onset of symptoms all got well, whether they had a segment of bowel to be resected or whether the strangulation was so early that resection was not indicated. Of those who entered the hospital within the first twenty-four hours of onset and were operated on during the second twenty-four hours, 25 per cent died. After twenty-four hours have elapsed following the onset of symptoms, then the greatest of care must be exercised in attempting to make this differential diagnosis, because if the patient does have a strangulation obstruction and operative treatment is further delayed then that patient has just that much less chance to live. On the other hand, if the patient has a simple obstruction, if vomiting has been profuse and the patient is badly depleted, too early surgical intervention without adequate restitution of fluids will result in a mortality rate which for that simple obstruction will be excessive. Any corrective operation on the badly distended patient in a late stage may well be fatal. Therefore in certain late cases we may have to ignore possible intestinal strangulation and treat them on a basis of simple obstruction in order to save those patients whose bowel is viable, realizing that at this late stage death will probably result if strangulation is present regardless of the treatment instituted. Sudden onset of pain is the outstanding symptom of acute small bowel obstruction. The early scout film is the greatest single confirmatory evidence which we have. However, the interpretation of that scout film is difficult.

DR. EVERETT I. EVANS, Richmond, Va.: My feeling is exactly that which has been stated by Dr. McKittrick; that is, the general management of all bowel obstruction, if seen early. Our chairman's address brought out again the fact that with the advances of physiology we tend to remove our interest more and more from anatomic problems; we tend also to ignore the true surgical problem and at times worry too much about equilibration of the patient with fluid before surgical operation. I should say, however, that we must be slow to decry any effort to minimize the importance of the work that has been done in this field, especially by Dr. Wangensteen and his group. We should add that in patients with obstruction of the small bowel who are seen early, whether or not one is certain of strangulation, it is becoming the experience of more and more groups that early surgical intervention is essentially giving better results. We see each year about 50 to 55 patients with simple obstruction of the bowel in our hospital groups, and the resident staffs are being encouraged to follow what has been outlined so well here by Dr. McKittrick and in his published papers, that the best procedure is early surgical operation. It doesn't take long to administer proper amounts of fluid in those patients with simple obstruction, especially when they are seen early. Surgeons cannot do much about this problem unless the general practitioner or internist who sees most of these patients in the early hours attempts to diagnose early obstruction and gets them to the hospital in time. Unfortunately, in our experience, even the loss of, say, six to eight hours has been too great, and we have had fatal issue when that amount of time has been lost. Early diagnosis, therefore, and early surgical intervention in obstruction is in our opinion important.

Exposure to Mustard Gas.—The toxic effects of mustard vapor on the respiratory tract have been well known since July 1917, when the Germans first used this gas against the Allies. Gilchrist and Matz have described the residual effects in American soldiers eight to ten years after mustard gassing. Less widely known is the fact that many persons employed in the handling of mustard gas and exposed to small quantities of the vapor over a prolonged period of time may sustain damage to the respiratory mucosa which may leave them partially or totally disabled. This statement is based on two and one-half years of observation in the medical department of an industrial plant where over 200 patients have been treated for both the acute symptoms and the residual effects of mustard gas exposure.—Morgenstern, Philip; Koss, Frank R., and Alexander, William W.: *Ann. Int. Med.*, January 1947.

CHANGES IN THE VISUAL FIELDS CONFIRMED BY PATHOLOGIC DIAGNOSIS

DONALD J. LYLE, M.D.
Cincinnati

Ophthalmoscopic examination may reveal papilledema and atrophy in intracranial lesions. It may show vascular and retinal changes indicative of cerebral or general systemic disturbances and it may not show anything, even with involvement of the intracranial portion of the visual system, the so-called cases of cerebral blindness. Another aid to the diagnosis of intracranial lesions, possibly of greater importance, is a thorough study of the visual fields. Here again the examination may be negative, but it should be pursued routinely and with care. When defects in the visual fields are found they may frequently aid in determining the location and nature of a lesion and its activity and prognosis.

Further aid in diagnosis may be had by study of the reactions of the pupil and the state of the extraocular muscles and by observation of the function of the tissues innervated by the trigeminal and facial nerves as they concern the eye. Other neurologic observations may be of assistance. Examination of the spinal fluid, the blood and the urine may be of value. Roentgenologic studies are frequently helpful. Electric encephalography with its localizing and diagnosing possibilities will no doubt develop into another source of diagnostic importance.

In order to derive the maximum benefit from studies of the visual fields one must know the anatomic location, structure and disposition of the elements comprising the visual system. For this reason a brief review of the anatomy of the relevant part of the visual system is presented.

ANATOMY

From the ganglion cells of the retina axons of the third visual neuron pass, as the nerve fiber layer of the retina, to form the optic nerve which courses to the optic chiasm. Here semidecussation takes place, and the axons continue as the optic tract to arborize about the dendrites of the fourth visual neuron in the lateral geniculate body. Clinical lesions have clearly located the position of the fibers from the upper and lower, inner and outer quadrants of the retina and have fairly well indicated the position of the macular fibers. The axons from the macular area of the eye, forming the papillomacular bundle, enter the optic nerve in the temporal side of the papilla, displacing the upper and lower peripheral temporal fibers. These, in turn, crowd and somewhat displace the upper and lower nasal fibers. As the nerve approaches the optic chiasm the papillomacular bundle assumes a central position with the quadrants of the retina approximately represented in their proper relative positions. Passing through the chiasm the temporal retinal fibers continue in the optic tract on the same side, while the nasal retinal fibers cross over to the opposite side. The right half of each retina forms the right optic tract and the left half of each retina the left optic tract. The macular fibers in the papillomacular bundle also partially decussate as they pass through the chiasm to enter the dorsal portion of the optic tract.

Read before the joint meeting of the Section on Ophthalmology and the Section on Nervous and Mental Diseases at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

As the optic tract proceeds there is a twisting or torsion of all of the nerve fibers, the macular fibers assuming a superior position with a central wedge, the peripheral retinal fibers lying below. The upper peripheral retinal fibers are mesial to and slightly above the lower retinal fibers, which are laterally placed. This torsion proceeds along the course of the optic tract to the lateral geniculate body. In the optic tract fibers representing the retinal quadrants are apparently bunched at first and then separate and intermingle farther back. They terminate in the horseshoe-shaped lamellae of the lateral geniculate body in alternate layers, first from one eye and then from the other. The axons from the upper part of the retina pass to the mesial prong and those from the lower part of the retina to the lateral prong of the geniculate body. This grouping of fibers from one retinal area, especially forward in the tract, probably accounts for the incongruity in defects of the visual fields when lesions are located in the optic tract.

In the optic radiations, fibers spread out and spiral in various planes so that defects of a sector or quadrant of the visual field with small lesions are to be expected. The axons from the median half of the cells of the lateral geniculate body, representing the upper retinal fibers, pass as the upper optic radiations through the upper temporal, lower parietal and occipital lobes, lateral to the posterior horn of the lateral ventricle, to terminate in the sensory cortical visual area, the striate area, of the cuneus above the calcarine fissure. Axons from the lateral half of the geniculate body, as the lower optic radiations, first course forward and around the temporal horn of the lateral ventricle. This is known as Archambault's, Flechsig's, Meyer's or Cushing's loop. The fibers then proceed posteriorly through the temporal and occipital lobes to the visual sensory area of the cortex in the lingual gyrus below the calcarine fissure. The torsion of the fibers of the optic tract is neutralized by the spiraling of the fibers of the optic radiations, so that the upper part of the retina is represented by the upper radiations and cuneus and the lower part of the retina by the lower radiations and lingual gyrus.

The macular fibers probably pass in the optic radiations directly to the occipital pole and its vicinity. The discussion over sparing and nonsparing of the macula still continues. It is known that the macular fibers semidecussate at the optic chiasm and terminate at least for the most part at the posterior pole. Further details are not definitely established. Several reasons have been advanced for the sparing of the macula in lesions which should supposedly include it. Chief among them are the following:

1. There is a crossing of macular fibers in the region of the occipital lobe to the opposite visual cortex through the splenium of the corpus callosum. If this is the case these fibers might pass short of a lesion on one side and course to the opposite striate area.

2. There is a dual blood supply to the macular cortical area from the middle and posterior cerebral arteries. The probabilities are that sufficient circulation to the macular area is maintained by one nutrient vessel if the other ceases to function.

3. There is an extensive macular representation throughout the entire striate area. The inference here is that a lesion must be large enough to affect the entire visuoreceptive area before it can produce loss of macular vision.

4. The patient with loss of half of the macular field unconsciously fixes slightly to one side of the fovea, using a functioning paramacular area to compensate for the loss.

The sensory visual cortex of the occipital lobe, the striate area (area 17 of Brodmann), is joined by intragyral and intergyral fibers (arcuate fibers). These fibers also extend to the adjacent psychic visual cortex, which is also termed the parastriate and peristriate, or parareceptive and perireceptive areas (areas 18 and 19 of Brodmann). These areas are concerned with visual reception and recognition and with revisualization and visual comprehension. Still higher visual centers are those in the angular and supramarginal gyri in the lower posterior parietal lobe. Implication of these various so-called visuopsychic areas produces disturbances in visual perception and recognition, interpretation and evaluation and reaction to visual stimuli. Even though the visual object is seen by the sensory cortex, a disturbance or destruction in the adjacent higher visual areas renders the person blind to its presence or to its proper reception or evaluation.

CLINICAL MANIFESTATIONS

Defects in the visual field and other clinical manifestations of diseases of the visual system vary chiefly as they concern the location and type of lesion. The chief components of the visual system are the retrobulbar optic nerve, the optic chiasm, the optic tract, the optic radiations and the visual cortex. The types of lesions, for the sake of simplicity and organization, are loosely grouped into inflammations, tumors and vascular affections. Inflammations include a variety of conditions, some probably more primarily degenerative than inflammatory. Tumors include, besides neoplasms, other expanding growths, such as aneurysms, hematomas, abscesses, tuberculomas and gummas. Vascular diseases are produced chiefly by sclerotic and thrombotic vessels and, less frequently, by embolic occlusion. Angiospasms may also produce occasional vascular disturbances.

RETROBULBAR OPTIC NERVE

The retrobulbar optic nerve is involved chiefly in inflammations resulting in various types of retrobulbar neuritis which may be divided into extraneural neuritis or perineuritis and intraneural neuritis.

The perineuritis which affects the sheaths of the optic nerve is frequently an extension from the meninges of the brain or from infections of the orbit and the sinuses. The so-called chiasmatic arachnoiditis is a more or less localized form of meningitis usually caused by the coccic infections which involve the optic chiasm and intracranial portion of the optic nerve. The visual fields usually show unilateral or bilateral concentric or sectoral peripheral defects. Meningovascular syphilis produces another type of basal meningitis frequently affecting the prechiasmatic optic nerve. In these cases superior altitudinal loss in the visual field may occur. Tumors of the nerve sheath such as meningiomas and tumors in the neighborhood, both orbital and intracranial, either by direct pressure on or by interference with the blood supply, may produce peripheral changes in the fields. Sclerotic arteries and expanding aneurysms may act in like manner. Injuries to the optic nerves, which are especially vulnerable as they pass through the optic foramen, may produce changes in the visual fields.

Retrobulbar optic neuritis usually presents a central type of defect of the visual fields. The scotomas may be relative or absolute, or both. They may be paracentral, pericentral, cecocentral, sectoral or annular. With these central changes slight peripheral constriction is not uncommon. The changes in the central field may be an extension from perineuritis or they may develop from an infected infarct which forms a metastatic abscess. Systemic infections such as influenza and the exanthematous diseases may produce retrobulbar neuritis. The chronic infections such as syphilis, tuberculosis, arthritis and gonorrhea may produce lesions of the central optic nerve with changes in the visual fields. Syphilis frequently produces definite and progressive *concentric constriction of the visual fields.*

Probably the chief cause of retrobulbar optic neuritis is multiple sclerosis (disseminated sclerosis), one of the demyelinating diseases. This condition seems to have a predilection for the retrobulbar axons of the optic nerve. In these cases the lesions, and changes in the field, are usually unilateral, variable, mobile, fluctuating and fleeting. An acute type is that of transverse neuromyelitis optica of Devic, in which sudden and complete bilateral blindness occurs though one eye may be affected in advance of the other. There may be no change noted in the appearance of the fundi. Other types of demyelinating disorders are the acute disseminating encephalomyelitis usually caused by various infections and fevers and the encephalitis periaxialis diffusa of Schilder, a chronic form which is frequently located in the occipital lobe and optic radiations.

Some of the abiotrophic or early degenerative changes may affect the retrobulbar optic nerve. Leber's hereditary optic atrophy is a good example. It is definitely of a hereditary and sex-linked character and usually affects males. Central blindness frequently develops because of degeneration of the papillomacular bundle. At the same time concentric peripheral contraction may be noted.

Toxic amblyopias from exogenous poisons attack chiefly the subchiasmatic optic nerve. Some authors believe that the retina may also be affected, the axons of the optic nerve from the ganglion cells of the retina being secondarily affected. It is exceptional to find pathologic changes in either location. In the usual type of amblyopia there is a bilateral involvement of the central fields implicating the papillomacular bundle. Tobacco and lead are common examples of poisons having this effect. In tobacco amblyopia the scotomas are usually centrocecal and relative with absolute nuclei. Ethyl alcohol is usually associated with tobacco. Methyl alcohol is extremely toxic and produces permanent destruction of the optic nerve in those who survive. Lead and the inorganic compounds of arsenic produce bilateral defects of the central field frequently with some peripheral constriction.

Peripheral defects of the visual fields in amblyopia are found in poisoning with organic compounds of arsenic, in which there is frequently seen extreme bilateral concentric constriction. Quinine, in those with an idiosyncrasy for the drug, manifests similar changes. Aspidium is in this class.

Chronic types of retrobulbar neuritis are occasionally found. They may resemble toxic amblyopia and are frequently bilateral. The longer the condition persists the less chance there is of recovery with restoration of the areas in the visual fields which have been lost.

In retrobulbar inflammations of the optic nerve a thorough history is necessary *in order to determine the* presence of the infection or poison. Thorough laboratory tests are necessary as well as a roentgenologic examination of *the nasal sinuses, orbit, optic foramen* and prechiasmal area. Occasionally encephalograms may be helpful. Tumors and vascular lesions must be excluded.

OPTIC CHIASM

The optic chiasm is involved chiefly by pituitary tumors, although other neoplastic growths in the neighborhood may also affect it. Pituitary tumors usually first press on the lower mesial fibers of the chiasm, producing a defect in the upper outer quadrants of the visual fields. Frequently one side is in advance of the other. As the tumor expands the upper mesial fibers are affected, resulting in a bitemporal hemianopsia. Then the lower nasal fields become involved, and finally total loss of vision results. The loss in the visual fields usually develops counterclockwise in the field of the *right eye and clockwise in the field of the left eye.* The optic chiasm may be affected by other tumors in the neighborhood such as craniopharyngiomas and meningiomas of the sphenoidal ridge and tuberculum sellae. Tumors of the third ventricle may press forward on the optic chiasm, producing bitemporal and central defects of the visual fields.

In this same area sclerosis of the internal carotid artery as it lies against the optic chiasm may produce binasal or altitudinal defects of the fields. An expanding aneurysm *of the arteries in this location also may* involve the optic chiasm.

Inflammation of the meninges forming the chiasmatic cistern may produce defects of the visual fields, frequently of the altitudinal type. This is seen in chiasmatic arachnoiditis and meningovascular syphilis. Extension of retrobulbar optic neuritis may include the optic chiasm producing bilateral defects of the fields. Plaques of multiple sclerosis may also occur in the chiasm, usually resulting in bilateral scotomas.

In this area roentgenologic examination is usually of great importance. Expanding lesions, chiefly adenomas of the pituitary, produce deformities of the sella and erosion of the clinoid processes and the sphenoidal ridge and may produce shadows which are found chiefly in craniopharyngiomas and certain types of meningiomas and gliomas. Encephalograms and possibly ventriculograms may be necessary to reveal surface or internal disturbances in the cranial cavity. Neurologic and laboratory tests, especially in reference to the *pituitary and the autonomic nervous system,* are frequently of aid in establishing a diagnosis.

OPTIC TRACT

The optic tract is affected chiefly by tumors at the anterior end which are the same as those involving the chiasm. Farther back vascular lesions are usually more frequently found. Tumors of the third ventricle or the temporal lobe may involve the optic tract from within or from without.

The anterior part of the optic tract, as well as the optic chiasm, is supplied by many vessels from the circle of Willis. For this reason it is not apt to be involved in vascular diseases because of its good blood supply excepting from pressure of sclerotic vessels, aneurysm and clot. Farther back the tract is nourished chiefly from the anterior choroidal artery. A thrombosis of, or an embolus in, that vessel produces a homonymous hemianopsia, usually complete.

Because of the distribution of the visual axons in the optic tract changes in the fields are frequently in a sector or a quadrant and are homonymous. However, if the lesion is forward, bitemporal loss in the fields may be found. The edges of the defects in the visual fields are usually sloping and incongruous at the forward end, as the fibers from the crossing have not yet intermingled with the lateral fibers passing straight through the chiasm. The macular bundle of the optic tract may or may not escape the lesion. Forward it is more apt to become implicated, as it lies in the dorsal posterior part of the chiasm from which it passes into the dorsal part of the optic tract.

Inflammation from meningitis of various types, abscess and syphilitic and tuberculous infections may be found in the area through which the optic tract courses. These conditions are less frequently the cause of involvement of the optic tract than are tumors and vascular lesions.

Roentgenologic examination may reveal changes of diagnostic importance, especially at the anterior end of the optic tract, in conjunction with those conditions producing chiasmatic disturbances. As the tract skirts the hypothalamus, which contains the nuclei of the autonomic nervous system, defects in the visual fields may be combined with parasympathetic or sympathetic nervous symptoms. Diabetes insipidus is not uncommon, with involvement of the anterior part of the hypothalamus, and disturbances of heat regulation and blood pressure, among other manifestations, result from affection of the middle and posterior parts of the hypothalamus.

LATERAL GENICULATE BODY

In the lateral geniculate body isolated lesions have not, to my knowledge, been reported or recorded. Therefore involvement of the lateral geniculate body may be included in lesions of the posterior optic tract or of the beginning optic radiations. As the lateral geniculate body is at the retrolenticular end of the posterior limb of the internal capsule, its implication may produce homonymous hemianopsia along with sensory and motor disturbances by diseases of the adjacent superior peduncle of the thalamus and posterior limb of the internal capsule.

OPTIC RADIATIONS

In the optic radiations vascular diseases are the most frequent. As the radiations cover a great part of the superior temporal lobe, the posterior inferior edge of the parietal lobe and the occipital lobe, a large area is involved, so that many localities may be affected and rather large lesions may result. The anterior choroidal artery is the main vessel to supply the anterior part of the radiations, especially the lower visual fibers. In the middle portion of the radiations the middle cerebral artery and in the posterior radiations and visual cortex both the middle cerebral and the calcarine—especially the latter—branch of the posterior cerebral arteries are the nourishing vessels. Frequently thromboses of these arteries, and occasionally emboli, produce disturbances of the visual fields.

Visual field changes are not exceptional in tumors of the optic radiations. Tumors of the anterior temporal lobe affecting the lower optic radiations show defects in the upper part of the visual fields, frequently with some disturbances of audition and equilibrium. Farther back, the lower optic radiations are involved in tumors of the lower temporal lobe and the occipital lobe. Tumors of the upper temporal lobe, the lower posterior parietal and the upper occipital lobe affect the lower parts of the visual fields. In addition, visual hallucinations may occur if the lesion is on the dominant side (left side in the right handed).

Inflammations may affect the optic radiations. Occasionally a case of paraxial diffuse encephalitis of Schilder is seen in which plaques have been produced in the optic radiations. Some types of encephalitis may involve the radiations.

The defects in the visual field from radiation lesions usually show edges sharp and congruous. The macular fibers are usually spared, at least in part, and seem less likely to become involved the farther back the lesion occurs.

Ventriculograms may show an obliteration of a ventricle or its displacement. A pineal shadow also may indicate the presence of a lesion by its displacement. Meningiomas and oligodendrogliomas may produce shadows. Cardiovascular-renal and blood studies are of great importance, as most of the lesions are vascular. Injuries are not infrequent in this location and require thorough study by the ophthalmologist as well as by the neurologist and the neurosurgeon.

VISUAL CORTEX

Visuocortical lesions are also chiefly vascular. The chief arteries supplying this area are the middle and posterior cerebral arteries, of which the calcarine branch is the most important. Defects of the central part of the field usually indicate involvement of the posterior pole. Peripheral changes in the field are probably from lesions farther forward in the striate area. The upper lip of the calcarine fissure, the cuneus, when affected produces a homonymous defect in the lower part of the fields. A lesion in the lower lip of the calcarine fissure, the lingual gyrus, produces a homonymous defect in the upper part of the fields. Because the area of the posterior radiations and sensory visual cortex is relatively great, defects involving a sector or an indentation are seen usually at the inception of an expanding tumor. Vascular lesions frequently but not always produce a larger defect in the field immediately. Small scotomas of homonyous character may indicate a small lesion. If more centrally located in the field the lesion is farther back. Because there is a dual blood supply to the occipital pole, sparing of the macula is more frequent in defects in the fields due to cortical lesions.

Inflammations may involve the visual cortex. Here again toxins and poisons, viruses and bacteria and their products and metabolic and endocrine disturbance may act on the brain. In the sensory visual area loss in the visual fields or irritation is the result. Irritation may produce flashes of light or coarse hallucinations. Farther forward in the psychic visual areas irritation produces more complex visual hallucinations on the left side in the right handed. Visual illusions result from irritation to the psychic visual cortex chiefly from drugs, poisons and toxins.

When the parastriate or peristriate areas of the visual cortex are involved (areas 18 and 19 of Brodmann), visual perception, recognition and revisualization may be lost, especially on the dominant side. With involvement of the still higher centers in the angular and supramarginal gyri, higher visual activities are curtailed.

Loss of vision without changes in the fundus is seen in the functional diseases such as neurasthenia and hysteria. These disturbances will not be discussed.

SUMMARY

By way of generalization, in reference to defects in the visual fields, the following observations may aid in developing and supporting the proper diagnosis.

A. Locations

1. Inflammations are found chiefly forward in the retrobulbar optic nerve.
2. Tumors, especially neoplasms, are more frequently located in the area of the optic chiasm.
3. Vascular lesions more frequently affect the radiations and cortex.

However, tumors, inflammations, degenerations and vascular disturbances may involve any part of the visual system.

B. Onset

1. Inflammations usually produce fairly rapidly changing fields. The chronic infections show less rapid changes but rather a slow gradual increase. Multiple sclerosis produces a rather rapid defect in the field, frequently relative in character, which may, and usually does, disappear within a short time.
2. Tumors, usually neoplastic, grow relatively slowly. So do aneurysms, which, before rupture, act as do tumors. Abscesses, tuberculomas and gummas are usually more rapid in their development and are usually accompanied by inflammatory symptoms. Hematomas from trauma, bleeding tumors and ruptured aneurysms and other vascular disturbances are rapid in the production of loss in the visual fields.
3. Vascular diseases are frequently instantaneous but, as in the case of thrombosis, may give a few days' warning by producing relative and intermittent defects in the visual fields before the circulation shuts down. Hemorrhages and emboli are instantaneous.

C. Duration (prognosis)

1. Inflammations, as a rule, have a tendency to subside, so that the prognosis is relatively good. There is less chance of improvement the longer the defect in the field persists. Finding and eliminating the cause of the inflammation in time is an essential factor. Multiple sclerotic fields have a tendency to disappear in one location but may appear elsewhere. Defects in the visual fields from cerebrospinal syphilis do not, as a rule, improve but usually progress.
2. Tumors show gradual progress in changes in the visual fields unless the pressure is removed. They produce defects in the visual fields both by direct pressure on the nervous elements and by pressure on the nutrient vessels supplying these elements.
3. Vascular lesions behave according to type. There may be some improvement in cases of hemorrhage when absorption or surgical evacuation has removed the pressure. In the cases of thrombosis and embolus, if the blood supply cannot be reestablished the defect remains.

In closing, it might be well to make one or two observations on the charting of visual fields. If the patient is cooperative, targets or spotters of different size should be used with varied illuminations. The color tests may also be used. Frequently perception of color is affected before perception of white, and it thus determines earlier the relative defects in the fields. Reduction of perception of red-green may also indicate involvement of the conduction fibers. Reduction of the perception of blue may suggest cellular or nuclear loss of function. However, many investigators of reputation believe that color tests indicate no more than do white targets of various sizes and different illuminations. They believe that intensity of illumination, size of target and light wavelength of test object (white or color) have a certain equivalent in the visual field.

An important aid is the charting of the relative defects in the fields, especially as they border areas of absolute loss. Comparison of their change of size or width may indicate whether the condition is progressing or receding. These relative defects usually represent the visual structure which is not completely damaged but which has become involved by inflammation, edema, pressure or other factors interfering with its proper function. They will be the next to be destroyed if the condition is progressing and will change from a relative to an absolute defect. On the other hand, if the relative defect becomes narrower or disappears, leaving normal field adjacent to an absolute defect, the process is receding or has abated.

Clinicians are indeed fortunate if these more accurate studies of the visual field are possible. Only too frequently the patient, because of his impaired mental state produced by the condition which has caused the defect in his visual field, is beyond necessary cooperation. If the ophthalmologist could see these patients earlier he might be able to make a greater contribution to the proper diagnosis.

ABSTRACT OF DISCUSSION

Major John S. McGavic, Phoenixville, Pa.: Both the ophthalmologist and the neurologist can profit from a study in which clinical observations are confirmed by pathologic specimens such as Dr. Lyle has just presented. I wish that Dr. Lyle would give us his opinion about sparing of the fixation area in patients with hemianopsia. One important factor brought out by Dr. Lyle bears reemphasis. The areas of perception, recognition and interpretation (areas 17, 18 and 19 of Brodmann) are separately represented in the visual cortex, although they are integrated by intragyral and intergyral fibers. One may, therefore, be misled in interpreting defects in the fields because the patient may see and not recognize, may see and recognize but fail to interpret the image to the examiner, and so forth. Lesions in the angular and supramarginal gyri in the posterior portion of the parietal lobe produce symptoms bizarre to the patient and lead to confusion on the part of both patient and examiner. In other words, the psychic visual area may be involved alone or in addition to the receptive portion of the calcarine area. One must always keep in mind that the determination of visual fields is a subjective examination. Repetition of studies of the fields is therefore extremely important to insure accuracy as well as to follow changes in the defects in the diagnosis of ocular and neurologic disorders. After the liberation of American soldiers from the Japanese prison camps, one began to see many patients with nutritional amblyopia. The majority of these patients had normal peripheral fields with relative or absolute central or paracentral scotomas. The size and shape of the central and cecocentral scotomas varied tremendously, but practically all had cecocentral scotomas for red test objects. Despite all arguments for quantitative fields with variously sized white test objects, there can be no doubt that with these patients it was far easier and more satisfactory to elicit a defect when red test objects were used. Many patients with considerable reduction in visual acuity and with definite central scotomas showed nerve heads which were well within normal limits. These patients had learned to use their eyes to the best advantage—fixing just to one side of the object and shifting fixation rapidly to build a picture from several partial images. None of them complained about anything—all felt that their vision was better than it actually was. I should like to emphasize what Dr. Lyle said, that the ophthalmologist's contribution to diagnosis would be greater if he saw the patient earlier. There can be no question of this. It is too bad that there has not been more teamwork and trading of information between the ophthalmologist and the neurologist. It is my feeling that this teamwork should start between the residents on the neurology and eye services of our hospitals—and continue as they become attending staff members.

Dr. P. J. Leinfelder, Iowa City: At times, pathologic processes cause seemingly impossible symptoms. Bitemporal or homonymous hemianopsia may be caused by a dilated third ventricle which results from a shift of the anterior part of the ventricular system and a kinking of the aqueduct of Sylvius. In producing a homonymous hemianopsia, a frontoparietal tumor may act in two ways. The pressure may be on the ipsilateral tract by herniated brain substance in the region of the uncinate gyrus, or it may be contralateral due to transferred pressure which squeezes the tract between the brain stem and the compressed temporal lobe. Lesions of the internal capsule cause a homonymous hemianopsia with hemianesthesia, but only rarely is the lesion large enough to cause coexisting hemiplegia; if hemiplegia accompanies such a lesion, the accompanying coma precludes diagnosis of the visual loss. Hemiplegia and homonymous hemianopsia are the result of a lesion on the basal surface of the brain in the region where the optic tract swings around the cerebral peduncles and the contained pyramidal tracts. Pituitary tumor may exist without resulting in changes in the fields or without roentgenologic evidence of destruction of the sella. In an occasional patient the syndrome of cerebral tumor is fully developed, with choked disks and increased intracranial pressure but without localizing signs. Careful examination by all methods known to the brain surgeon fails to disclose a neoplasm or reason for the increased intracranial pressure. Such cases at operation reveal turgescence of the brain which is transient but recurring in nature. This syndrome has been named "pseudotumor." Some relief has been gained by trephination, but the choked disk may persist for months and years. I have observed such a case during a period of more than four years, during which time the elevation of the nerve head has been present at each examination but visual fields have remained normal. The textbooks state that temporal pallor is a pathognomonic sign of multiple sclerosis. Temporal pallor is a common physiologic finding and is of no diagnostic importance in multiple sclerosis unless it is accompanied by diminished central visual acuity, which means then that there has been previously existing retrobulbar neuritis which has destroyed some of the visual fibers, produced a real optic atrophy and a central scotoma.

Dr. Donald J. Lyle, Cincinnati: I wish to thank Major McGavic and Dr. Leinfelder for their kind discussion. Major McGavic asked one question which I have answered in my paper, but I did not read the paper. I will just read that paragraph briefly. [. . . Dr. Lyle read the paragraph in his paper commencing with the words "Several reasons have been advanced. . . ."] Those, I believe, are the chief ideas brought forth as to the sparing of the macula. There has been some other work developed, although I believe that includes the four chief causes at this time. I wish to thank you.

PROTECTION OF THE HUMAN BODY

Principles as Applied in a Restraining Harness for Aircraft Pilots

COMMANDER HOWARD R. BIERMAN (MC), U.S.N.R.
LIEUTENANT (jg) RUSSELL M. WILDER Jr., MC(S), U.S.N.R.
and
LIEUTENANT (jg) HARPER K. HELLEMS, MC(S), U.S.N.R.

During the past seven months investigations of the effects of impact forces on the human body have been carried out with the impact decelerator (fig. 1) previously described.[1] In an airplane crash the pilot or aircrewman is flung forcibly forward against his restraining harness. The impact decelerator produces stresses on the subject by jerking the harness backward against the abdomen and shoulders and offers a highly useful and convenient technic for studying impact forces of the order of magnitude of those which are believed to occur in an aircraft crash.

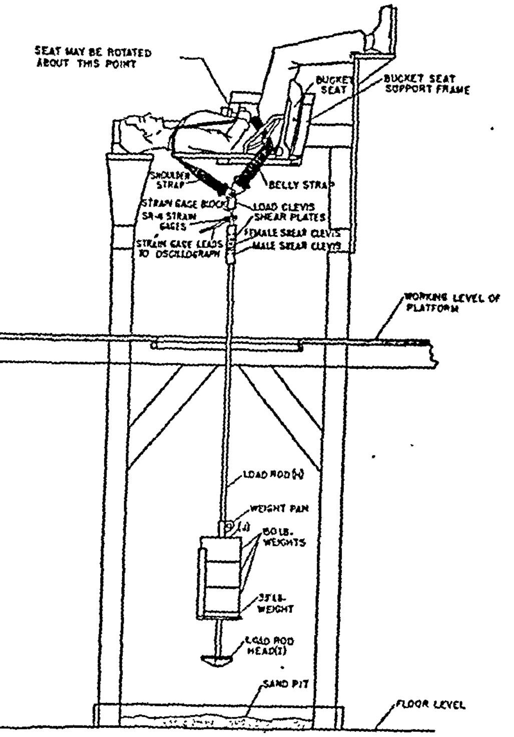

Fig. 1.—The Impact Decelerator: Impact forces are transmitted to the subject through the rod (H) and shoulder and belly straps by the arresting of falling weights (J) by the load rod head (I). These forces are measured by SR4 wire strain gages attached to the rod.

The conventional safety harness transmits impact forces to the subject over a relatively narrow area of body surface.[2] The forces transmitted to the body with this harness during an impact are unevenly distributed and are concentrated at the umbilicus and the clavicular areas, suggesting the need for modification. The first

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the United States Navy. The opinions and views set forth in this article are those of the writer and are not to be construed as reflecting the policies of the Navy Department.

[1] Bierman, H. R.: *Design of an Impact Decelerator,* Research Project X-630, Report no. 3, Naval Medical Research Institute, Nov. 30, 1945.

[2] Bierman, H. R., and Larsen, V. R.: Distribution of Impact Forces on the Human Through Restraining Devices, Research Project X-630, Report no. 4, Naval Medical Research Institute, Feb. 18, 1946.

modification (model A) employed a vest-type garment with an area of 156 square inches and distributed the forces over twice the area of the body covered by the conventional harness.[3] This harness, constructed of semirigid, drawn, heavy nylon fabric, was capable of offering increased protection against larger impacts.

The limit of tolerance of the human body to impact using the regulation type harness (area about 76 square inches) was found to be about 2,000 pounds impact produced by dropping 165 pounds from a height of 3 feet. When a semirigid vest-type harness (model A) was used (area about 156 square inches) the tolerable limit was increased to 3,300 pounds, obtained by dropping 165 pounds from 5 feet.

The criteria for tolerance of the volunteer subjects used in these experiments were the appearance of cutaneous ecchymoses or the initial suggestion of injury to ligaments, muscle or bone—the type of injury which occurs frequently in football. These clinical observations together with changes in the electrocardiogram and in the respiratory pattern, subjective complaints of the subject and observations of the investigator served to fix the end point of maximal tolerable impact. It was soon found, however, that the impact curve recorded by the strain gages followed a fairly characteristic pattern for any type of semirigid harness (fig. 2).

Figure 2 shows a strain-gage tracing of a 10,000 pound impact applied to a dummy in a semirigid harness. The impact was produced by dropping a 500 pound weight from a height of five feet, equivalent to 2,500 foot-pounds of energy. The duration of impact is 0.17 second, but its maximum force occurs during the first 0.06 second. The sharp peak represents the type of impact force which the subjects have found to be least tolerable. A human being probably could not survive this impact of 10,000 pounds. Since an effective, protective harness must prevent this full impact from reaching the subject, this drop of 500 pounds from five feet was used for the final test purposes. A reference to the "maximal load" means this drop involving 2,500 foot-pounds which produces a 10,000 pound peak impact on a dummy using a semirigid harness.

Since the torso is asymmetric and since various parts of the body are more resistant to impact than others it is essential that provision be made to distribute the forces to the parts most capable of absorbing the energy of the impact. This distribution of impact forces must also be such as to minimize shearing effects on the body caused by uneven forces.

Further investigations with the impact decelerator and high speed cinematography yielded information concerning the effects of the initial part of the impact. The rate of loading was found to bear a relationship to the maximal tolerable load.[4] Rapid application of the impact causing the peak to occur in less than 30 or 40 milliseconds was exceedingly uncomfortable. In general, the slower rates of loading were preferred by the subjects.[5]

Another series of experiments indicated that those undergoing impact prefer the force to be evenly applied. Irregularities of the force proved to be particularly disagreeable.

The potential energy produced by an impact is proportional to its force multiplied by the distance traveled. Large peaks of force can be effectively avoided by slightly increasing the distance of travel. Undrawn nylon elongates in direct proportion to the kinetic energy applied. It has insignificant recoil. This material can be made so that it begins its stretch at loads below the injury threshold.

The lower curve of figure 2 represents a desirable and practical impact force whose characteristics are based on previously obtained data. The curve rises slowly. It has no irregularities, and it stays below the injury producing level. Its plateau is maintained for 0.15 second before it drops off to the base line. Its duration is longer, 0.24 second as compared to 0.17 second, but it represents the same "maximal load." Although its plateau is 3,250 pounds, it occupies the same area on the graph (contains the same energy) as the shorter impact whose maximum peak is 10,000 pounds.

It was felt that an impact which closely followed such a force-time pattern would be least likely to produce injury. Three harnesses (models A, B and C) were constructed in an attempt to approximate this curve and thereby allow the human body to withstand safely larger impact forces. Model B harness was used in the initial stages of development of the principles for protection against impacts. It was discarded in favor of a later and more finished model.

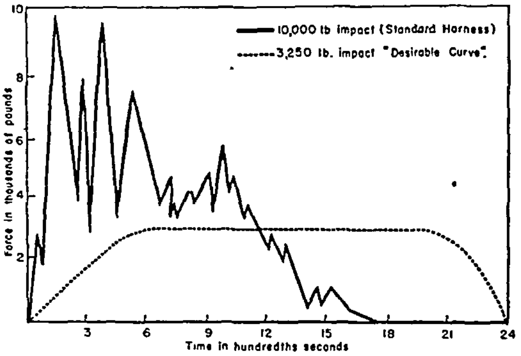

Fig. 2.—Strain gage tracing of an actual 10,000 pound impact on a dummy contrasted with "desirable" impact force curve.

EXPERIMENTAL DESIGN

The impact decelerator was used to produce impacts to test the new restraining harness (model C) on volunteers. A "maximal load" was utilized. Measurements of the total force as well as of the pressure exerted by the harness against the anterior wall of the chest were recorded by small wire strain gages.

The model C harness covers the thorax and abdomen and has an area of 156 square inches (fig. 3). The harness is a combination shoulder strap and lap safety belt. It is in the form of a vest which has two straps leading from the shoulders and two straps leading laterally from its abdominal portion. The vest portion of the harness which is in contact with the thorax and abdomen is made of undrawn nylon duck (90 by 61 count by yarn). The strap material is made of undrawn nylon[6] only in the lengthwise direction. The cross filler thread is drawn nylon and does not stretch significantly during impact. The vest material stretches slightly in both directions on impact, permitting the garment to form-fit the torso and thus distributing the load in proportion to the pressure exerted by the body contacting it. Since undrawn nylon has a lower elastic constant than conventional harness webbing it will stretch more before the draw load is reached and will, therefore, apply the load more gradually. As soon as the impact load reaches the draw load of the undrawn nylon strap material, which is placed at an impact load known to be safe for human beings, the strap will increase in length in an amount related to the force developed. It will continue to elongate without recoil until it reaches a limit beyond which it stretches like drawn nylon (fig. 5).

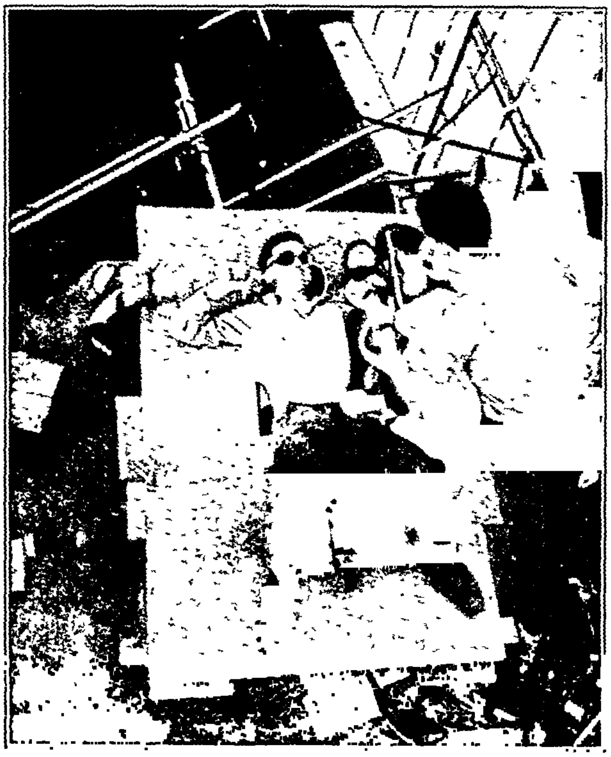

Fig 3.—Subject wearing model C harness on the impact decelerator. Measuring devices (ear photo cell and respirometer) are also shown.

RESULTS

Impact forces were gradually increased to a "maximal load" and were easily tolerated by volunteers using the undrawn nylon (model C) harness (fig. 5). The effect of this impact on the subjects while wearing the model C harness was considerably less distressing than in previous tests using a semirigid harness with loads one-fifth this magnitude. The subjects also felt that the impact load was applied more gradually and with less shock than if a semirigid harness had been used. The volunteers reported that the load during impact was distributed more comfortably over the torso. Specific areas of pressure were not observed beneath the harness. Untoward reactions were not apparent. The subjects stated unanimously that they preferred the "maximal load" with the model C harness to 2,000 pound impacts (165 pounds dropped from 3 feet) with the semirigid (model A) harness.

Physiologic data recorded during and after varying impacts with different harnesses are to be presented in a separate report.[7] These data closely parallel the subjective reactions of the volunteers. With the model C harness physiologic changes did not occur comparable to those seen after impacts delivered when the semirigid harness was worn.

With the factors presented in the summary of this report incorporated in one harness (fig. 4) it has been possible to protect a person against 500 pounds dropped 3 feet with but 6 inches of decelerative distance. The material in the model C harness begins to stretch at a draw load of 2,200 pounds. With "maximal loads" the model C harness stretched 13 inches. Using undrawn nylon that begins to elongate at higher draw loads, the harness stretch for the "maximal load" will be less.

COMMENT

The effectiveness and adaptability of a vest-harness device for the protection of persons in aircraft against linear acceleration depends on the character of the force encountered and many other factors that can be unequivocally evaluated only by experimental aircraft crashes. The data outlined comprises the underlying principles employed to secure maximal protection against the type of force produced by the impact decelerator and the demonstration of the comparative value of different types of harness to achieve this type of protection.

6. Absorbs large amounts of energy with insignificant recoil

Fig. 4—Diagram to illustrate features of protection embodied in new (model C) harness. The schematic time force curves apply to forces as produced with the impact decelerator.

The conventional harness protects effectively against impacts of 2,000 pounds on the impact decelerator. Subjects using a harness of larger area over the thorax and abdomen have tolerated impacts of 3,000 pounds. When such a harness incorporates the features of maximal area and more equal distribution to the torso, the human can tolerate greater impact loads. If the rate of loading is slowed and irregularities in the force applied are removed, the injury threshold is still further raised. And if, in addition to the above factors, a small distance of controlled stretch without recoil is employed, a "maximal load" can be effectively absorbed without injury.

[7] Bierman, H. R.; Wilder, R. M., Jr., and Hellems, H. K.: The Physiological Effect of Compressive Forces on the Torso, Research Project X 630, Naval Medical Research Institute, Report no. 8, Dec. 19, 1946.

It is known from previous studies[8] that a person wearing a semirigid harness can successfully withstand impact loads only as high as 3,000 pounds without tissue damage. Attempts to exceed this force have led to injuries.

The basic protective principle in the model C harness is the stretching of the undrawn nylon without recoil under a draw load below the injury threshold for body tissues. The excess energy which would otherwise cause tissue damage is absorbed by the harness without injury to the wearer. It is this type of protective deceleration involving either the stretching of material or the absorption by material compressed through distances of the order of 6 inches that no doubt enabled persons as reported by DeHaven[8] to survive falls estimated to exceed 200 g. (The symbol g denotes the force of gravity.)

It follows then that the draw load for a protective harness for use in aircraft should be set at a reasonable level below that of the injury limit. This is the critical consideration. Higher draw loads will decrease the amount of decelerative distance but at the expense of probable tissue damage.

Fig. 5.—Closeup of shoulder strap. Note the difference in distance between the ink marks in the stretched and unstretched portions of the strap. Prior to impact these marks were equidistant.

ADDENDUM

An investigation of experimental aircraft crashes has been completed since this paper was given. Nine aircraft were crashed into a solid dirt barrier at approximately 100 miles per hour simulating the forces involved when a stalled aircraft crashes head on into the ground from 300 to 500 feet. The planes decelerated within 5 feet. Both the aircraft structure and anthropomorphic dummies in the aircraft were instrumented. High speed cinematography permitted further visual and physical analysis. Severe, nonuniform accelerations of 0.05 to 0.15 second were found with the conventional semirigid straps. The decelerating vest lengthened the duration and reduced the peak force significantly, similar to its action and effectiveness in the laboratory. Full results of this study are in preparation.

The available seat-to-gunsight distance varies for all aircraft[9] and is the critical factor toward limiting the maximal protection one can afford such personnel utilizing the principle of added deceleration.

In a fatal airplane crash whose duration approaches 1 second, it is believed that impacts of lethal magnitude are produced during only a brief portion of the total time (fig. 7). It is felt that adequate protection against these accelerative peaks is the first essential in the saving of lives otherwise lost through crash injuries.

In an aircraft crash the forces are applied first to the aircraft structure and then transmitted to the pilot through the structures leading back to the seat and its attachments to the restraining devices. During such transmission of force, there is undoubtedly an absorption of energy so that the force reaching the subject is less than the initial force at the point of the impact of the aircraft.[10] The amount of energy that can be absorbed by the aircraft structure during a crash is unknown. Whatever this absorbed energy, which may be termed factor x, it acts to protect the person. Hence, if the model C harness protects the wearer against 40 g, it should then suffice to protect him against impact forces developed in aircraft that crash with forces exceeding 40 g by the unknown structural absorption factor x. Therefore, it is apparent that the cockpit must be made sufficiently strong to resist forces of at least this magnitude.

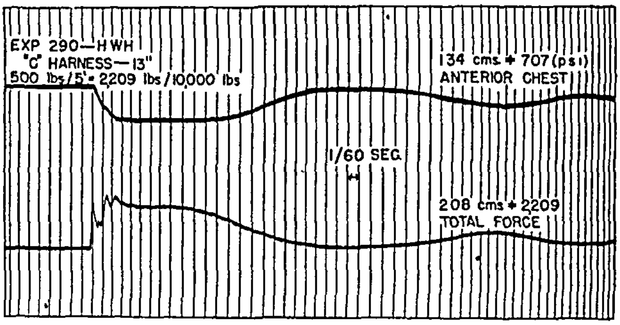

Fig. 6.—Strain gage recording on subject H. W. H. wearing model C harness of a maximal impact produced when 500 pounds was dropped from 5 feet on the impact decelerator. The upper curve represents the pressure record produced by the vest pressing against the anterior wall of the chest; 1.34 cm. of deflection of the curve is equivalent to 7.06 psi. The lower recording is a total force curve as measured by the block gage; 2.08 cm. of deflection represents 2,209 pounds impact force. Timing lines are one-sixtieth second. It can be seen that at no time does the subject receive more than 2,209 pounds impact despite the fact that this same load would produce 10,000 pounds on a dummy had a semirigid harness been used. (Note: psi, pounds per square inch.)

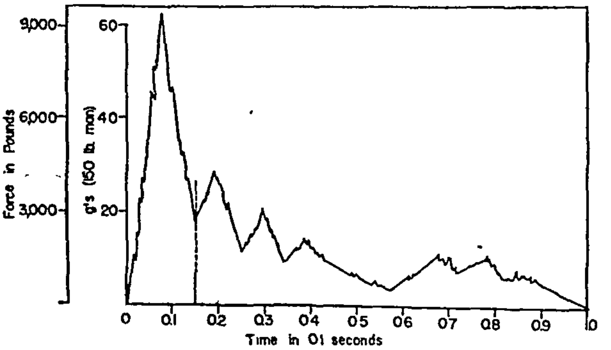

Fig. 7.—Hypothetic illustration of the impact forces occurring during an aircraft crash of 1 second total duration. The injury threshold is exceeded only during the first 0.15 second.

SUMMARY

1. A restraining harness for aircraft pilots has been developed which has successfully protected volunteers against 2,500 foot-pounds delivered on the impact decelerator by dropping a 500 pound weight 5 feet. This impact force expended in 0.15 second on a dummy

enclosed in a semirigid harness is featured by 10,000 pound peaks as measured by strain gages.

2. The factors which contribute to the effectiveness of this harness are: (*a*) distribution of the impact load over a large body area; (*b*) distribution of the impact load to regions of the body best able to withstand high impact forces; (*c*) gradual rate of application of force due to high initial elasticity of the material; (*d*) dampening out of small irregularities during the period of impact, and (*e*) the property of the material to elongate inelastically when the applied force reaches a predetermined tolerable limit, permitting the absorption of large amounts of energy.

The principles outlined in this report may be applied to protection against many other types of large accelerative forces that may be encountered, for example, in automobile and train accidents.[11]

GONIOTOMY FOR CONGENITAL GLAUCOMA

Urgent Need for Early Diagnosis and Operation

OTTO BARKAN, M.D.
San Francisco

Congenital glaucoma in the past has resulted in a high percentage of blindness, due to lack of an adequate operation.

Anderson[1] stated: "There is no division of opinion regarding the severity of the visual loss and its progressive nature in spite of treatment. Seefelder found that 81 per cent of his series of 60 eyes were quite or almost blind. Ten of the 46 patients were in blind asylums. In only 15 was the corrected vision as good as 6/60"

In 1941, I reported on 17 patients with congenital glaucoma operated on by goniotomy.[2] In the present article results of goniotomy performed on 76 eyes are recorded. Goniotomy preserved useful vision in most cases. When combined with early diagnosis, it gave excellent visual results. A plea is made for early diagnosis and prompt adequate operation.

The observations and conclusions on diagnosis, pathologic conditions and surgical treatment presented in this communication are based on my experience during the past ten years in a series of 51 children and infants afflicted with infantile or congenital glaucoma. Of the 76 eyes operated on by goniotomy, in 66 the operation normalized pressure and maintained or restored vision over periods ranging from one to ten years. In 10 eyes the operation was unsuccessful. Eleven eyes, 10 of which had been previously trephined, were in an advanced degenerative stage which did not permit goniotomy. All patients were private patients who lent themselves well to careful analysis. Detailed operative technic including modifications recently reported[3] will be published in a future article.

DEFINITION AND TERMINOLOGY

The term "congenital glaucoma" is used to imply that the cause is congenital rather than that the condition is clinically evident at birth. Although symptoms are often present at birth, in many cases they do not occur until the age of 2 or more months. For this reason the term "infantile glaucoma" also appears suitable, because it implies that the condition may occur at any time during infancy. The enlargement of the eyeball suggested by the time-honored term "buphthalmos" or "ox eye" represents an advanced stage of the condition. Such a term tends to make for a fateful delay in diagnosis since, as is known, the majority of cases of infantile glaucoma show congestive symptoms long before the eye is manifestly enlarged. Diagnosis should, if possible, be made soon after the onset of congestive symptoms and should not be deferred until enlargement of the bulbus becomes obvious. The term "congenital or infantile" glaucoma would appear appropriate, therefore, for the purpose of early diagnosis and treatment, because it suggests onset at birth or during infancy and does not connote pronounced bulbar enlargement as does "buphthalmos."

DIAGNOSIS

The early signs in congenital or infantile glaucoma are often of a congestive and irritative nature. In the present series out of 87 eyes, 70 showed congestive symptoms at the time of onset.

The congestive symptoms which are caused by increased pressure consist of (1) corneal cloudiness, minor or extreme; (2) hyperemia of the bulbar conjunctiva, slight to moderate; (3) photophobia, which may be extreme; (4) epiphora, and (5) blepharospasm.

In 30 eyes cloudy cornea was present at birth. In 35 eyes the onset of congestive symptoms appeared between the first and fourth months. In 11 eyes the onset was between the fourth and ninth months. Some increase of pressure and enlargement of the eyeballs was present before congestive symptoms appeared, since these children are often described as having had *especially beautiful (i. e. large) eyes. This appearance* in otherwise normal-looking eyes should arouse suspicion. Usually, however, the onset of congestive symptoms is the feature which calls attention to the condition; the onset is often rapid and may be even sudden. Such was the case in 6 infants in this series in each of whom cloudiness of the cornea was discovered by the mother when the infant was taken up in the morning; the eyes had been clear the previous night. In 1 case the cloudiness was discovered when the infant was taken up from its afternoon nap.

The cloudiness of the cornea is often associated with photophobia, which may be so intense that the eyes cannot be opened except in the dark. For this reason it was impossible to obtain preoperative photographs in many cases. Figure 1 illustrates moderate cloudiness of the cornea. Figure 2 shows the same patient postoperatively. Figures 3 and 5 illustrate preoperative congestive signs of minor degree which permitted of photography. Figures 4 and 6 show the same patients postoperatively. In the case of T. M., aged 11 months, the eyes were of normal appearance until the age of 6 months. When after whooping cough and pneumonia the mother noticed cloudy corneas. From then on the child was extremely photophobic. It spent its life playing at night in a dark room and sleeping during the day. When brought for examination it kept its head buried in its mother's bosom. A glimpse of the eyes could be obtained only by separation of the lids by force because of the intense blepharospasm. Ten days after the operation the corneas were clear and the photophobia almost absent. Figure 7 shows this patient sixteen months after the operation. The corneas are clear; vision is excellent.

---

[11] With the decelerative distance permitted in these cases, one may apply such information to any linear accelerative force and predict with reliability how much protective accelerative distance is needed for such contingencies as a blow on the head, falling on a deck, running into the edge of a table or an automobile bumper hitting a leg, provided, of course, one knows what the accelerative curve is to be for that instance.

Read before the Section on Ophthalmology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946

[1] Anderson, J. R.: Hydrophthalmia or Congenital Glaucoma, London, Cambridge University Press, 1939, p 104.

[2] Barkan, O. Operation for Congenital Glaucoma, Am. J. Ophth. **25**: 552-568 (May) 1942

[3] Barkan, O. Goniotomy, Am J. Ophth. **28**: 1133-1134 (Oct.) 1945.

The corneal cloudiness and lack of luster which are characteristic of the early stage can be shown by staining with fluorescein sodium to be due chiefly to a disturbance of the epithelium. I am convinced that it is largely this disturbance, consisting of roughening of the corneal epithelium, which is the cause of the irritative symptoms and photophobia; these in turn seem to be aggravated by exposure to air and light.

A physician who first sees the child with these congestive symptoms is apt to make a diagnosis of conjunctivitis, blepharitis or keratitis He is not prone to think of glaucoma because the term "buphthalmos" is associated in his mind only with enlargement of the eyeball The resulting delay in arriving at the correct diagnosis and institution of proper and adequate treatment may be tragic, for by the time that the eyeball is strikingly enlarged the patient is usually well on his way to partial or total blindness Therefore, in every case in infants in which irritative phenomena or corneal cloudiness is present, even though the bulbus does not appear enlarged, glaucoma must be suspected and intra-ocular pressure tested with a tonometer

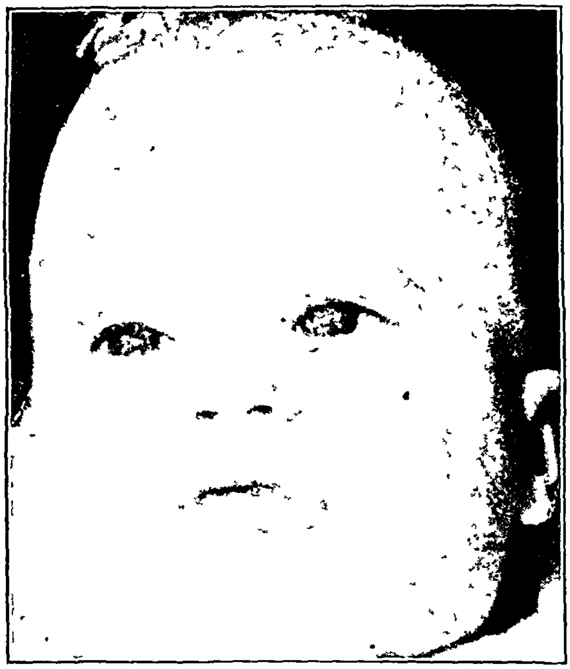

Fig 1 (preoperative)—P O Q, aged 5 months, first seen July 25, 1944 Cloudy corneas developed six days before Patient showed slight photophobia and tearing since birth Pupils are in miosis due to three instillations of 5 per cent solution of prostigmine every three hours

The tension should always be measured with the patient under ether anesthesia which must be deep at the moment of measurement. Other general anesthetic agents have proved unsatisfactory. It has been found that the tension may vary 10 to 15 mm of mercury, depending on the depth of anesthesia, and that only when the patient was completely relaxed was the tension constant. Cases have been observed in which increased tension due to insufficient anesthesia led to an incorrect diagnosis of congenital glaucoma. In the present series of cases in which the pressure was elevated, 5 per cent solution of prostigmine was instilled in the eyes every three hours, and goniotomy was performed as soon as possible

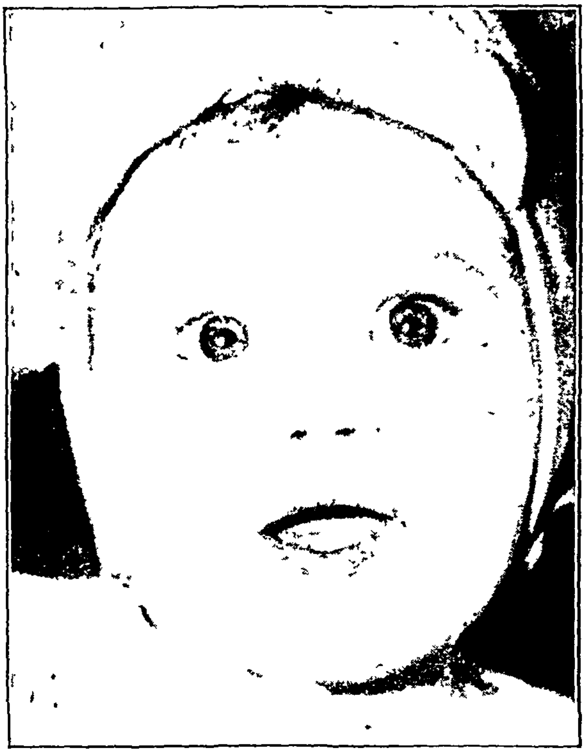

Fig 2 (postoperatively)—P O Q, aged 2½ years From Aug 9, 1944, to Oct 2, 1945, four goniotomies were performed on each eye The last operation on the right eye was nine months ago, and on the left eye eighteen months ago Note clear corneas, normal appearing eyes and complete absence of symptoms Tension (McLean) March 17, 1946, was 34 mm in the right eye and 34 mm in the left eye without use of miotics Refraction was —2 00 sphere in each eye Ophthalmoscopic examination showed normal appearance of heads of optic nerves

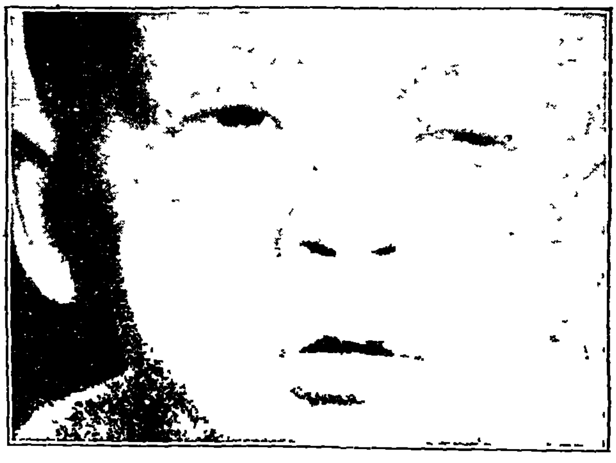

Fig 3 (preoperative)—T C, aged 11 months, first seen July 10, 1942 Two months previously, on May 11, 1942, cornea of left eye became cloudy overnight There were photophobia and tearing The eye could be opened with difficulty, the bulbus was enlarged

In cases in which the cornea is sufficiently transparent one finds on careful gonioscopic examination characteristic evidences of congenital glaucoma in the angle of the chamber

CAUSE OF REDUCED VISION IN INFANTILE GLAUCOMA

Anderson[4] has pointed out that the cause of the reduced vision in infantile glaucoma is usually regarded as being atrophy of the optic nerve and one or more disorders in addition. In the present series atrophy of the optic nerve and others of these disorders were not the original cause but were the result of progressive enlargement of the eyeballs and of degeneration of tissue associated with the late, advanced stage of the disease. The primary cause of reduced vision in most cases in the series was a disturbance of the cornea. This disturbance begins with corneal cloudiness (edema?). It appears to coincide with the onset of increased intraocular pressure. If allowed to persist it is followed by permanent scarring of the cornea with associated irregular astigmatism and ensuing amblyopia of greater or less degree. Those patients in whom the corneal cloudiness was relieved within a few days after its onset acquired acute vision. Therefore, prompt relief of corneal cloudiness seems to result in two great benefits: 1. The degree of permanent residual corneal scarring and irregular astigmatism is minimized. 2. The duration of the impediment to development of vision during the period of growth is shortened, and consequently the opportunity for development of amblyopia is minimized.

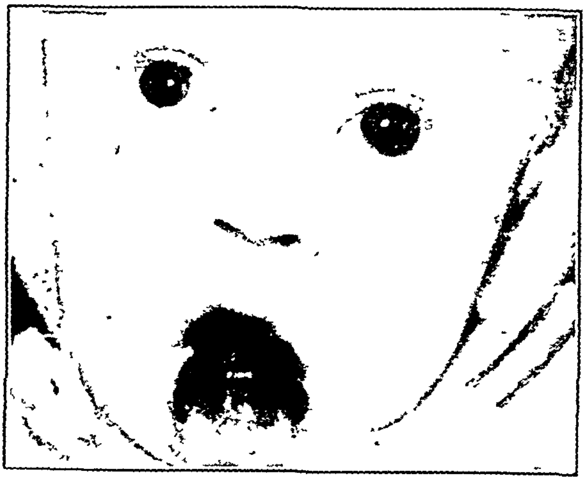

Fig. 4 (postoperative).—T. C., aged 14 months, three months after goniotomy was performed on the left eye, on August 21, 1942. Note clear cornea. The left eye is slightly enlarged, but is otherwise normal in appearance. On May 25, 1944, twenty-one months after the operation, tension (McLean) was 29 mm. in the right eye and 28 mm. in the left eye without use of miotics. Refraction was as follows: right eye, −1.00 cyl. ⊂ −1.00 cyl., axis 180; left eye, −3.50 sphere. Gonioscopy of the left eye showed stripping of angle in one third of its circumference. Ophthalmoscopic examination showed wide shallow excavation of the head of the optic nerve of the left eye but no atrophy.

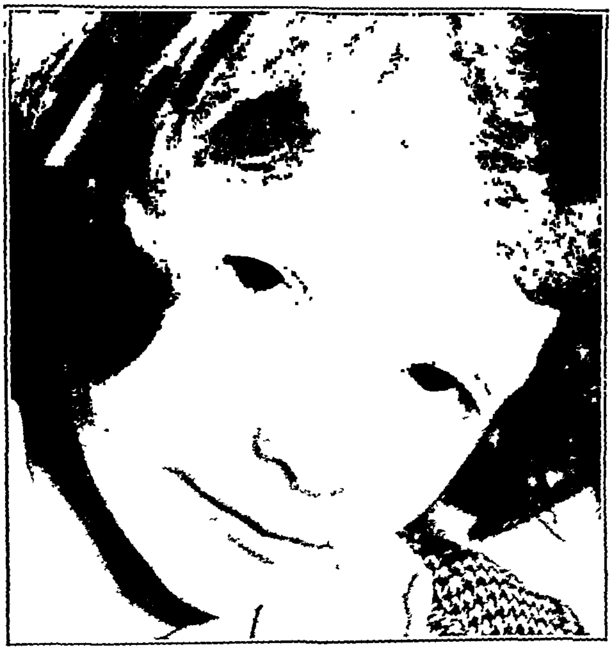

Fig. 5 (preoperative).—J. V., aged 6 years. Since birth left eye was slightly larger and cloudy, there was some tearing. When first seen May 10, 1943, tension in right eye was normal, and in left eye was + 1 to + 2. Photograph shows patient avoiding light. There is some tearing.

EFFECTS OF HYPERTENSION

1. *Corneal Cloudiness.*—Corneal cloudiness is the main characteristic of the congestive phase of the early stage and is at this stage completely reversible surgically and in some cases by miotics. The cloudiness usually occupies the central area. In cases of severe disease it may cover the entire cornea, leaving only a strip adjoining the limbus clear. Fluorescein sodium stains such corneas. Prolonged exposure to air, such as occurs when the blinking reflex is prevented while the patient is under general anesthesia, increases the cloudiness and staining within a few seconds; if the lids are kept closed for a few minutes these decrease. That the corneal lesion is at least partially dependent on exposure is confirmed by its characteristic localization in the zone of the palpebral fissure.

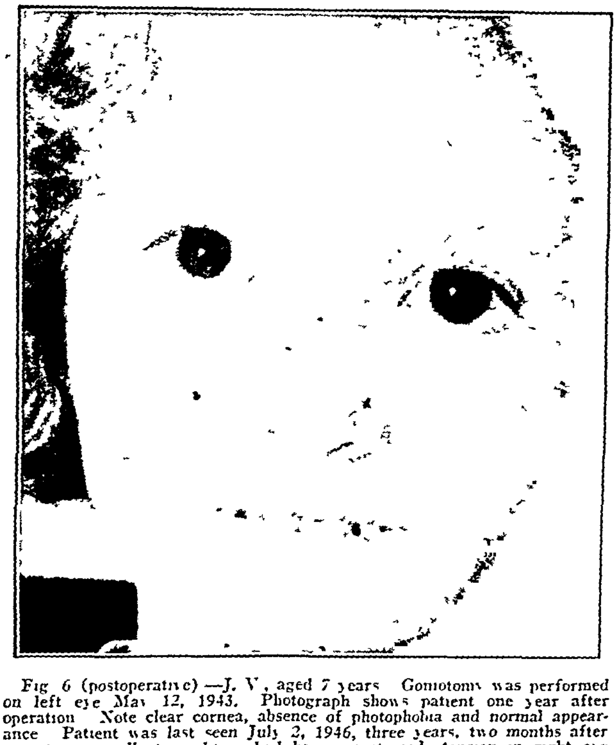

Fig. 6 (postoperative).—J. V., aged 7 years. Goniotomy was performed on left eye May 12, 1943. Photograph shows patient one year after operation. Note clear cornea, absence of photophobia and normal appearance. Patient was last seen July 2, 1946, three years, two months after operation; excellent condition had been maintained; tension in right eye was 31, in left eye 33 (McLean), without miotics; media were clear; ophthalmoscopic examination showed wide shallow excavation of head of optic nerve not extending to the rim; color of disk was good. Vision without correction, in right eye, is 0.8; in left eye, 0.4. With correction, vision in left eye is −0.50 sph. ⊂ −0.75 cyl., axis 90, = 0.6 and J 2.

The roughened epithelium appears to be the cause of the irritative symptoms, which in turn are aggravated by exposure to air and light. These irritative symptoms promptly disappear after normalization of pressure.

---

[4] Anderson,[3] p. 105.

coincident with the simultaneous restoration of corneal luster and epithelial integrity. Clinically the child's comfort closely parallels the epithelial integrity. Patients presenting high intraocular pressure and good corneal luster are usually comfortable and show no trace of photophobia or other irritative signs. Patients presenting lower pressure and poor corneal luster display irritative symptoms. The tolerance of the cornea to increased pressure manifests great individual variation. In some cases in which the tension is 50 mm. (McLean) the cornea may remain clear and irritative symptoms be absent during the course of many months; in others the development of the same degree of tension may immediately produce definite cloudiness and irritability.

Cloudiness of the corneas at this early age sometimes is associated with nystagmoid movements. In 2 cases these were relieved by clearing of the cornea. To illustrate: J. McL., born with cloudy corneas, presented pronounced nystagmoid movements when first seen at the age of 5 months. Three weeks after normalization of pressure in both eyes by goniotomy, these had greatly decreased. They disappeared almost entirely in the course of the next several months. In the case of J. H., aged 3 months when first examined, corneal cloudiness had developed two weeks previously. During the interval of fifteen days which elapsed between operations on the two eyes nystagmoid movements made their appearance. Two weeks after operation on the second eye, when pressure was normalized and the corneas were clear, these disappeared.

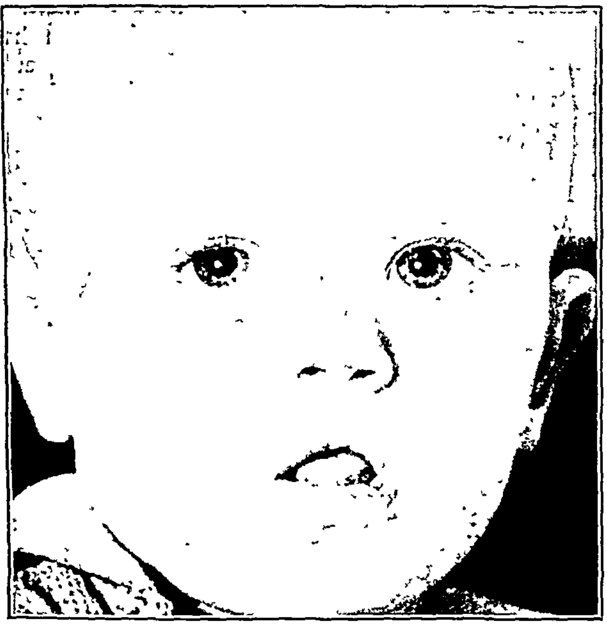

Fig. 7 (postoperative).—T M, aged 11 months, first seen July 14, 1943. After whooping cough and pneumonia at the age of 6 months both corneas became cloudy and photophobia was extreme, so that the eyes could not be opened in daylight. Goniotomy was performed six months after onset of symptoms, on the right eye on May 17 and on the left eye on May 20, 1943. Nine days after the operation the corneas were clear, eyes were open and patient tolerated light well. Eyes were normal in appearance except for slightly increased size There was no sign of corneal opacity, but retinoscopy showed slight irregular corneal astigmatism There was myopia of approximately — 2 00 sphere. On Sept 27, 1944 (sixteen months after the operation), tension (McLean) was 29 mm, in the right eye and 20 mm in the left eye without miotics In June 1946 (three years after the operation) a letter from Texas reported patient's condition to be excellent to date

Cloudiness of the cornea also requires quick relief (1) because of the rapidity with which it interferes with the development of vision and (2) because the longer it exists the denser and more extensive will be the ensuing permanent scar. The present series shows that corneal cloudiness can be relieved and that in most cases formation of a permanent corneal opacity and development of amblyopia can be prevented in great measure by early diagnosis and prompt operation.

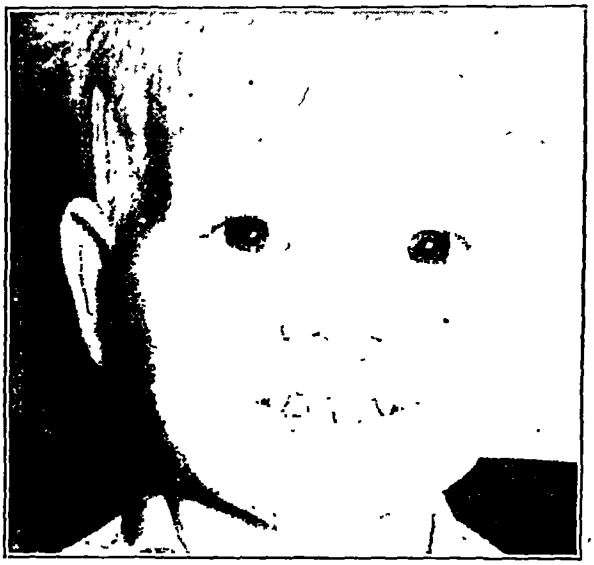

Fig. 8 (postoperative).—H. B., aged 7 months when first seen on June 28, 1939 Three months previously the cornea of the left eye had become cloudy. Tension in the right eye was 20 mm and in the left 90 mm. (McLean). Goniotomy was performed on the left eye on June 29, 1939. Drops of 5 per cent solution of prostigmine were instilled every three hours in both eyes On Aug 7, 1939, the tension (McLean) during ether anesthesia was 50 mm in the right eye and 31 mm. in the left. The cornea of the right eye was cloudy. Goniotomy was performed on the right eye. Three days after the operation the cornea of the right eye was clear. On Nov. 27, 1939, three months after the operation the tension (McLean) in the right eye was 22 mm and in the left was 22 mm without miotics. On Aug 12, 1942, when the patient was aged 3 years 9 months, vision of the right eye without correction was 0 5, and of the left was 1/200 When the patient was last seen, on June 12, 1946, when he was aged 7 years, 7 months, his condition was the same, and *the tension was normal The right eye was emmetropic, the left eye* myopic — 3 50 sphere The reduced vision of the left eye appeared to be due to amblyopia which developed during a transitory period of strabismus Binocular fixation was present.

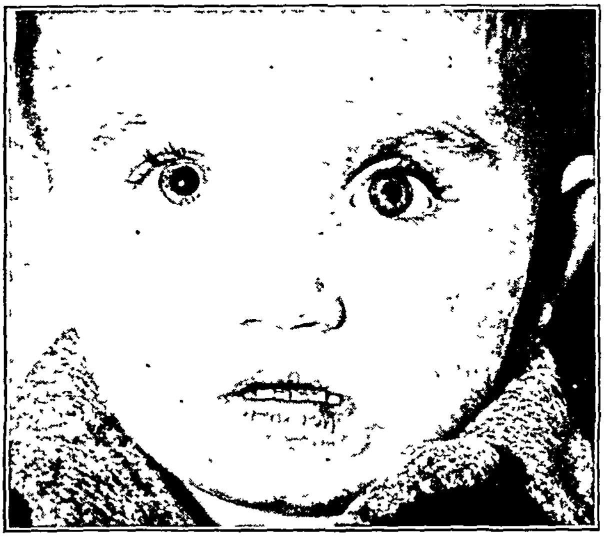

Fig 9 (postoperative) —B O'S, aged 4 years, first seen July 20, 1945 The left eye had been lost through trephine six months before The cornea of the right eye was clear, tension (McLean) with miotics was 70 mm Ophthalmoscopic examination showed glaucomatous excavation of the nerve head to the rim with slight pallor temporally. Vision was excellent, and visual fields were grossly normal Goniotomy on the right eye with the contact glass was performed on Oct 12, 1945 Three months afterward tension (McLean) in the right eye was 26 mm without miotics

2. *Permanent Scar.*—The cloudiness becomes a permanent scar. This "late" milky opacification develops from the original reversible congestive cloudiness of the

cornea when the latter has lasted sufficiently long to cause permanent damage to the corneal parenchyma. The prolonged distention per se may also be a factor in its formation, or both factors may be operating concurrently. This type is reversible in part only.. It involves chiefly the anterior layers of the corneal parenchyma. The epithelium shows normal to fair luster and does not stain with fluorescein sodium if the eye is in a noncongestive phase. There is, in certain of these cases, a relative absence of congestive symptoms because compensation has taken place. Pressure may actually be less than in the earlier stage, perhaps partially due to thinning of the tunics of the distended eye and possibly also to increased permeability of the occluding persistent meshwork in the angle resulting from stretching. The latter may be the mechanism, as has been suggested, which accounts for some of the rare cases of spontaneous arrest.

3. *Amblyopia.*—It is essential for the physician to keep in mind that a cloudy cornea during the first year of life, unless promptly relieved, retards the proper development of central vision at a most critical time.

The role of amblyopia is well illustrated by the case of J. McL., mentioned in a preceding paragraph, in whom normalization of tension by goniotomy at the age of 5 months resulted in considerable clearing of the cornea and in pronounced reduction of nystagmoid movements. In the case of H. B., aged 2 years, pressure in both eyes was normalized by goniotomy at the age of 7 months. One eye showed a slight residual permanent corneal opacity, as a result of which the eye became temporarily convergent at the age of 2. Some amblyopia resulted in this eye, since it was impossible to obtain the cooperation of the parents for adequate occlusion of the fellow eye. Vision with correction at the present time in the right eye is 5/10 and in the left 1/200. Binocular single vision has been maintained (fig. 8). These cases illustrate the susceptibility of the development of visual function to normal entry of light through the refractive media in the first year of life. They stress the urgency of prompt and adequate surgical intervention. They also show the need for diligent continued observation after pressure has been normalized, in order to detect beginning strabismus, which could rapidly induce amblyopia unless proper treatment with complete occlusion of the fellow eye is instituted.

4. *Glaucomatous Atrophy of the Optic Nerve.*—Glaucomatous atrophy of the optic nerve was the exception in this series. It occurred only in those few cases in which normalization of pressure was unduly delayed. In the case of B. O'S. (fig. 9), the patient did not come to operation until the age of 4½ years. The left eye had been lost due to atrophy following a trephine operation performed at the age of 4 years. The right eye carried a pressure of 50 mm. (McLean) while under the influence of miotics. It showed pronounced glaucomatous cupping of the nerve head to the rim. Because the cornea was clear excellent central vision had developed. This has been maintained since normalization of pressure by means of goniotomy performed one year ago. It is interesting to note, incidentally, that the excavation of the nerve head almost disappeared after normalization of pressure. In the case of B. P., who was first seen when 5 weeks old, repeated goniotomy and other operations were unsuccessful on 1 eye for two years; by the time the pressure was normalized optic atrophy had occurred. In the case of L. L., aged 3 years, bilateral trephination with total iridectomy had been performed at the age of 8 months without permanently reducing the tension. Cyclodiathermy also failed permanently to reduce tension. When the patient was 3 years old goniotomy was performed; pressure was normalized in both eyes, congestive symptoms which had persisted until this time were completely relieved and the corneas cleared considerably. Moderate reduction of vision was found to be due in part to faint corneal scarring with irregular astigmatism and in part to glaucomatous atrophy which had occurred as a result of the protracted period during which the pressure was increased. One may hope that early goniotomy will aid in relegating to the past the tragic sequelae of uncontrolled infantile glaucoma.

Ruptures or tears of Descemet's membrane, which are prominently referred to in the literature describing the pathologic anatomy of "buphthalmos," were absent in this series of infantile glaucoma. All patients were examined with a loupe and hand slit lamp and with the ophthalmoscope during ether anesthesia; some were also examined with the corneal microscope and hand slit lamp. Several were reexamined with the Gullstrand slit lamp in later years when they were old enough to cooperate. In my experience tears of Descemet's membrane in infantile glaucoma do not occur before pronounced distention and degenerative changes have taken place. These conditions did not exist at the time goniotomy was performed in this series, which probably accounts for the absence of tears. If this observation is correct, rupture of Descemet's membrane plays no role in diagnosis at the time when diagnosis is of therapeutic importance.

RESULTS

The results of goniotomy[5] in congenital glaucoma are summarized in the following table.

Goniotomy in Congenital Glaucoma

Number of infants and children	51
Eyes operated on by goniotomy	76
Successful (pressure normalized; vision maintained or restored)	66
Unsuccessful	10
Eyes in which goniotomy was not applicable	11

It has been my custom to prescribe miotics three times daily for two months after surgical intervention. The result of the operation was considered successful when intraocular pressure was never higher than 35 mm. of mercury with the McLean or 21 mm. with the Schiötz tonometer three months after operation, no miotics having been used during the two weeks preceding measurement of the pressure.

In the cases with successful result the time elapsed from the date of operation varied from six months to ten years. There were recurrences in 2 eyes, mentioned in the next paragraph. In the oldest case (2 eyes) the operation was done ten years ago; 5 eyes were operated on seven years ago; 8 eyes six years ago; 21 eyes from four to six years ago; 11 eyes from two to four years ago; 9 eyes from one to two years ago, and 10 eyes from three to twelve months ago.

---

[5] Goniotomy in infants and in adults are two distinct operations which differ in rationale, technic and effectivity. In infants the operation, which has been developed to a relatively satisfactory conclusion, consists of removing occluding fetal meshwork from the angle. In adults, in whom it has not yet shown an adequate degree of consistent efficacy to recommend its employment except in the occasional case, its objective is to incise the angle wall, that is the trabeculum itself. For this reason it is suggested that the term goniotomy be applied only to the operation performed on infants, and goniotrabeculotomy or trabeculotomy to the procedure carried out on adults.

The recurrence of increased pressure in 2 eyes was relieved by a further goniotomy in both instances. In F. W. pressure increased in the left eye eight years after operation. In J. McL. pressure increased in the left eye four years after operation. Gonioscopic examination showed that the stripping of the angle had been insufficient.

Repeated operations were necessary in 22 eyes before the pressure was permanently normalized. One operation sufficed in 45 eyes. In some cases, for example in that of P. O'Q. (fig. 1), goniotomy was performed four times on each eye before permanent normalization was attained. The ultimate result was excellent. I believe that it is better to err on the conservative side and partially strip the angle with safety on repeated occasions than to attempt to do an extensive stripping at one operation at the cost of greater hazard. Cases in which repeated operations were required before permanent normalization was attained are not listed as recurrences.

The operation was performed under the contact glass on 20 eyes. On 56 eyes the operation was performed without the contact glass because of corneal cloudiness.

In 8 eyes which had been ineffectively trephined goniotomy normalized tension.

Advantages of the operation are its relative lack of hazard, the absence of cosmetic disfigurement and preservation of a round central freely reacting pupil.

One of the disadvantages of the operation is the need of repetition in one third of the cases before permanent normalization of the tension is obtained. Another is that although the principle of the operation is simple its performance with consistent success requires a considerable degree of experience and highly trained assistance.

The hazards of the operation are excessive hemorrhage or iridodialysis if the root of the iris is incised. This hazard has been diminished by a preliminary deepening of the anterior chamber with isotonic solution of sodium chloride or air.[6] Infection, as in any other intraocular operation, is a possibility, but I have not encountered it. A severe reaction occurred in 1 case which could be considered an infective iritis. As always the operations on the eyes had been on different days, in this instance after an interval of three weeks. The condition cleared after eighteen days, leaving in one eye a small central opacity of the anterior capsule; in the other an anterior adhesion produced an eccentricity of the pupil. The tension was normalized, and it is evident that useful vision is developing. Sympathetic ophthalmia has occurred in no case up to the present time.

Before concluding I should like to state that my colleagues in San Francisco and in various parts of the country have referred these patients to me and that the Children's Hospital in San Francisco has been helpful in its cooperation.

CONCLUSIONS

Cloudy cornea and other congestive symptoms due to glaucoma are often present at birth. However, the onset of symptoms may not occur until the age of several weeks or months. In these cases, the onset is often rapid and may be even sudden. Occasionally, it is slow and manifests itself only by gradual enlargement of the eyeball and few or no signs of irritability. When the onset of increased pressure is rapid, congestion produces roughening of the epithelium which makes the eye unduly sensitive to light, causes epiphora and gives the cornea a cloudy appearance. At this time an incorrect diagnosis of conjunctivitis, keratitis or blepharitis is often made and valuable time may be lost. If the increased pressure is reduced by goniotomy soon after discovery of the condition, the symptoms can be relieved and the pressure in most cases permanently normalized with resulting useful vision and normal appearance. Even if the increased pressure and corneal cloudiness are allowed to persist for some months, operation may still normalize tension and relieve most of the cloudiness. However, the obstruction to development of central vision during a portion of the first year of the child's life and the residual scarring which usually persists may result in some degree of amblyopia. When normalization of pressure is further delayed, increasing distention and injury to the optic nerve add their quota to impending blindness.

SUMMARY

Congenital glaucoma in the past has resulted in a high percentage of blindness, due to lack of an adequate operation.

Goniotomy, performed at this writing on 76 eyes afflicted with infantile glaucoma, preserved useful vision in most cases. In 66 eyes pressure was normalized and vision maintained or restored over periods ranging from one to ten years. In 10 the operation was unsuccessful. When combined with early diagnosis it provided excellent visual results.

A plea is made for early diagnosis and prompt adequate operation by goniotomy.

The symptoms of increased intraocular pressure in congenital glaucoma may be present at birth, or their onset may be rapid or even sudden during the first few months of infancy. The symptoms consist of cloudy cornea, photophobia and other signs of irritation and congestion. Diagnosis should be made as soon as possible after onset of congestive symptoms and not deferred until enlargement of the eye is evident. Pressure should be measured with a tonometer with the patient under ether anesthesia which must be deep at the moment of measurement in order to avoid recording false values.

The appearance of congestive symptoms is prone to lead to a faulty diagnosis of blepharitis, conjunctivitis or keratitis, causing loss of valuable time and bearing tragic consequences.

The initial cloudiness of the cornea is associated with roughening of the corneal epithelium. This disturbance of the cornea is the chief cause of the irritative symptoms and photophobia which are further aggravated by exposure to air and light. If the corneal cloudiness is allowed to persist, it is superseded by permanent scarring with associated irregular astigmatism and ensuing amblyopia of greater or less degree.

Glaucomatous atrophy of the optic nerve was the exception in this series of infants and children. It occurred only in those few cases in which normalization of pressure was unduly delayed. In infants it is not

---

nearly so urgent to protect the head of the optic nerve from pressure as it is to relieve cloudiness of the cornea.

If soon after its inception increased intraocular pressure is normalized by goniotomy, transparency of the cornea is almost completely restored and maintained, and vision is afforded the opportunity to develop. When this is borne in mind, the urgency of prompt relief of increased pressure is evident.

490 Post Street.

ABSTRACT OF DISCUSSION

Dr. Meyer Wiener, Coronado, Calif.: Dr. Barkan's method of incising the trabeculae so as to permit a flow of aqueous into *Schlemm's canal gives the best promise of favorable results* in congenital glaucoma. This is especially true if one is able to operate in the early stages before complete closure of the canal takes place. Dr. Barkan lays particular stress on corneal cloudiness as a clue to the early diagnosis of congenital glaucoma. *This must not be confused with rupture of Descemet's membrane due to pressure on the globe during delivery.* In this case, however, the cloudiness would not disappear during the day as in the cases of glaucoma. I wonder if Dr. Barkan has ever used a couple of small, bent hairpins to separate the lids instead of the ordinary lid retractors, which give a great deal more room and which I found to be more satisfactory in every way. An objection to real deep anesthesia in measuring the tension of infants is that the eyes diverge and rotate up, so that one cannot place the tonometer in the exact center of the cornea, which is essential for exact readings. I see no more objection to the local instillation of an anesthetic in the infant, combined with first stage anesthesia, than there would be in the adult. I question the statement that amblyopia is due to nonuse alone. I have seen a case in which the operation was done forty years after the development of the cataract, with resulting 20/20 vision. I have never seen a true glaucomatous, undermined cup disappear under any circumstances, and it is hard for me to conceive how it can occur, although I would hesitate to question the author's statement to this effect. I am glad that the author makes the distinction between goniotomy in the infant, which consists of removing the occluding fetal membrane from the angle, and goniotrabeculotomy in the adult, the object of which is to incise the angle wall—that is, the trabeculum itself. This would also answer the question put by *Dr. Allen as to whether the operation should be called goniotomy* or trabeculotomy. The results obtained by Dr. Barkan in his operations for congenital glaucoma are so far beyond those of any method heretofore used that one can safely predict that his method will be universally adopted for this type of glaucoma, *which, in my experience, gave less promise with the* methods available before than any other type of glaucoma. For the purpose of handling cases of congenital glaucoma alone, Dr. Barkan has made one of the outstanding contributions to ophthalmic surgery in modern times.

Dr. Dohrmann K. Pischel, San *Francisco: Dr. Barkan* gives us information on 88 eyes in 51 patients, all observed by him. Of these, 76 were operated on by him personally. Thirty-six of the cured eyes have had tension normalized for a period of over four years. While the time is too short to be certain that a final answer has been provided to this difficult problem of hydrophthalmia, the results shown us today should make us all hopeful that we are at last on the track of the correct solution. The general opinion is that the prognosis in this disease is poor. More or less complete blindness in the affected eyes has been the usual fate. Therefore, a large series of good results should give us hope that these patients can be helped if treated properly. There has been a general misunderstanding as to how the operation of goniotomy is performed today. It was first thought that an incision is made in the angle, a direct opening being made into Schlemm's canal. This is not the case. In these hydrophthalmic patients there is an embryologic rest of spongy tissue in the angle which prevents the aqueous from reaching and filtering through the trabeculum. This operation aims at stripping off or wiping off sufficient of this tissue to open enough of this angle to allow normal filtration. The two main points of the paper bear emphasis, the importance of early diagnosis and of early operation. Patients operated on in the first year seem to do best. I have had the opportunity of seeing several of the patients with whom Dr. Barkan has been successful, each with good, clear corneas.

Dr. Thomas D. Allen, Chicago: Dr. Barkan has done us a service in describing the early signs and symptoms of infantile glaucoma, and especially in emphasizing the fact that the intraocular tension *must be determined with the patient under deep* general anesthesia. Some years ago we were having difficulty in comparing the tensions of the patients in one room and in another. One of the assistants lay down on a bench; I took his tension, and then asked him to squeeze his eye. Meanwhile I held his lids open carefully so that there was absolutely no pressure on his eye, and the tension immediately went up some 20 points, from a perfectly normal reading to about 40. If this happens in adults, how much more likely is it to happen in a little baby? We all know the stage of excitement during the induction of general anesthesia. If the *gross muscles of* the body are in a state of spasm, one cannot be sure that the ocular and orbital muscles are relaxed. Deep anesthesia is necessary for intraocular tonometry in babies. I have occasionally attempted the same operative procedure, but have not had nearly as many cases as Dr. Barkan. My first difficulty came with the first patient on whom I attempted the operation —a blind girl with numerous elongated peripheral anterior synechiae, which I cut. Much bleeding followed from the capillaries in some of these synechiae. I should never have attempted it in such a case. My greatest objection to this operative procedure is that several operations are often necessary. Sometimes several operations are necessary in other types of surgery, too, but usually when other decompression operations are attempted, one operation suffices. I agree that the operation is seldom effective after the eyeball has been enlarged for some time. We so seldom see and recognize the situation before enlargement has taken place that possibly that is the reason *we have not had such great success as Dr. Barkan. One should* not attempt goniotomy without careful gonioscopy. Only by carefully studying our cases can we select the proper treatment. With careful operative technic, I feel sure that the average skilled surgeon will find this operation a great help in the pre*vention of blindness.*

Dr. Edward B. Shaw, San Francisco: Congenital glaucoma is infrequent in occurrence, but we are deeply grateful to Dr. Barkan for the education which he has given us on the importance of this subject. We were formerly content to feel that *this was an abnormality seldom seen and that if it was encountered* there was so little to do about it that the pediatrician need not be much concerned. Dr. Barkan's work has called to our attention the diagnostic features of this abnormality and has impressed on us the importance of prompt and adequate therapy. I suppose that in the past most of these patients have eventually come under the care of a good ophthalmologist, but I am fearful that many of them have been temporized with too long as having either infections or metabolic disturbances and that a considerable and regrettable loss of time has occurred. Now that we have been educated to the importance of this emergency and to the proper operative care I have been particularly impressed with the success of the end results. There *is in all of pediatrics no more delightful result than to see such* a patient after operation with good vision who had the prospect of neither seeing well nor of looking well.

Dr. Peter C. Kronfeld, Chicago: I should like to put myself on record as a recent convert to the idea of goniotomy as the specific operation for the type of *congenital glaucoma* in which a layer of embryonic tissue covers the anterior angle wall. This layer of embryonic tissue may be thin and on casual examination with the gonioscope may escape attention, but in most cases of congenital glaucoma such a layer is present. Again we have to ask ourselves the question: Is "goniotomy" the proper term for it? The way it is practiced now, it is a stripping of the trabecular area without any actual incision. I believe it will help matters if Dr. Barkan would describe the operation, exactly the way in which he does it now. It is clear to me that goniotomy as it is practiced now gives much better results than the iridencleisis. There are definite successes with iridencleisis, but the frequency of those successes is much lower than that in Dr. Barkan's series. I should also like to apologize to my colleague from Chicago, Dr. Allen, whose paper before the meeting of the American Ophthalmological Society in 1944 I had the pleasure of discussing. At that time Dr. Allen presented a case of hydrophthalmos which he had successfully treated with goniotomies. The gonioscopic picture in that case resembled that after a cyclodialysis, and in my discussion I erroneously arrived at the conclusion that Dr. Allen had cured that patient with a cyclodialysis which he had done by a rather devious route. I now believe that the principle of that operation was the principle of goniotomy—namely, the stripping of the trabeculum. A dissecting spatula introduced into the anterior chamber from an angle toward the front will accomplish such a stripping more easily and extensively than a dissecting spatula introduced from behind. Goniotomy represents a definite progress in the treatment of hydrophthalmos.

Dr. Otto Barkan, San Francisco: Dr. Wiener's suggestion of the hairpins appeals to me as a good one. Disappearance of a cup after normalization of pressure is mentioned in Anderson's book. There was one such case in this series. I use the contact glass if the cornea is transparent. It is a great comfort in cases of monocular patients to operate under the glass and be assured that one will not get a hemorrhage. All patients with transparent cornea reacted excellently to the operation under the glass and did not require repetition. I have tried air as an aid to goniotomy, but in the adult the loss of magnification is a handicap. How it will turn out in congenital glaucoma remains to be seen. I am obliged to Dr. Pischel for calling attention to the stripping of the angle and to Dr. Allen for his remarks on the technic of goniotomy. Dr. Kronfeld brought up the question of the name of the operation, "goniotomy." It is true that it is not an incision. In the first cases I did incise, but there are definite handicaps if one gets an adhesion of the root of the iris to the incision in the angle wall. I now use a rather dull-pointed knife with the intention not of making a counterpuncture, but merely of stripping the embryonic tissue from the angle wall. In none of these cases have I seen an internal dialysis except possibly in one. In adults it is true that the reduction of pressure following goniotrabeculotomy may be the result of an internal cyclodialysis. That is not the intention of the operation, however; the intention in adults is actually to incise the trabeculum. In infants the intention is to strip the angle of fetal tissue. I should also like to thank Dr. Shaw for bringing up the pediatrician's point of view, which is important because so many of these infants are first seen by the pediatrician, and he should be aware of the possibility of glaucoma.

Physostigmine.—No drug employed in the practice of ophthalmology offers such a fascinating story to the medical historian as physostigmine (eserine). By the irony of fate this substance, which was used as an ordeal poison by primitive peoples, later proved to be one of the most effective agents in therapy of the eye. The natural product from which the drug was derived is Physostigma venenosum (Balfour) or Calabar bean. After extensive experimentation and observation, the active principle physostigmine was isolated by Fraser in 1863 and made to serve a great variety of medical therapeutic needs. Foremost among these was oculotherapy, and at present eserine (physostigmine) maintains an unchallenged place as a miotic.—Rodin, Frank H.: Eserine: Its History in the Practice of Ophthalmology, *Am. J. Ophth.*, January 1947.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 475)

(Note.—*Following is the sixteenth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of The Journal. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in The Journal. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—Ed.)

CHAPTER 16. *The Reorganization*

1900-1901

1900

ATLANTIC CITY

The year 1900 marked another turning point in the life of the American Medical Association; now came the transition from adolescence to adulthood. This was the beginning of the reorganization!

THE JOURNAL INDEX

The index published in 1899 attracted general attention, the only unfavorable criticism being that the book was now so bulky that there ought to be three volumes a year instead of two. This suggestion was adopted about forty years later. The editor suggested in reply to his correspondents that it might be well to bind the index separately.

In 1900 there were some articles reflecting the newer researches on malaria and the relationship of the mosquito to malarial infections. Bacteriology and parasitology were finding their place in medical science.

DEFENSE OF RESEARCH

At the meeting in 1898 a resolution had been introduced that a committee of five be appointed by the President at his leisure to cooperate with similar committees from other bodies to consider the desirability of formulating plans for the dissemination of knowledge of the value of experimental research in the progress of the science and art of medicine. The committee was appointed in 1900; it included Drs. H. C. Wood of Philadelphia, chairman; W. J. Mayo, Rochester, Minn.; F. H. Wiggin, New York City; J. F. Fulton, St. Paul, and C. A. Powers, Denver. This committee was to be the beginning of the work in defense of animal experimentation carried on so successfully by the American Medical Association since that date.

COMMITTEE ON SCIENTIFIC EXHIBIT

At the same time the President of the Association appointed a special committee to look after the Scientific Exhibit; this first committee included Drs. Joseph Stokes, Morristown, N. J., chairman; F. B. Wynn, Indianapolis, secretary; Alfred Stengel, Philadelphia, and W. W. Fox, Atlantic City.

PROPRIETARY MEDICINES

The interest in proprietary medicines had not died; the forthcoming meeting of the Pharmacopeial Convention stirred the editor of The Journal to a consideration of means by which editors could be guided in excluding from their advertising pages products which did not meet the standards of ethics of the medical and pharmaceutic sciences. "The difficulty," said the editorial, "has always been to know where to draw the line." A literal interpretation of professional ethics applied to the patronage and advertising of medicinal articles would exclude the vast majority of them. The editorial on proprietary medicines aroused correspondence indicating that the medical profession was ready for a movement toward scientific standards in the prescribing of remedies.

The announcement of the annual meeting was a reminder of the variety of representation in the Association. The scientific sections had now reached twelve, including

Practice of Medicine
Surgery and Anatomy
Obstetrics and Diseases of Women
Materia Medica, Pharmacy and Therapeutics
Ophthalmology
Laryngology and Otology
Diseases of Children
Physiology and Dietetics
Neurology and Medical Jurisprudence
Cutaneous Medicine and Surgery
State Medicine
Stomatology

There were many applications for places on the scientific programs. It became apparent that some means of restricting the total amount of material to be presented would have to be developed.

An article by P. Maxwell Foshay, editor of the *Cleveland Journal of Medicine*, was devoted to medical ethics and medical journals. He called attention to the multiplicity of such publications which lived primarily by the support of proprietary medicines. "The greed for advertising patronage," he said, "leads the editor only too often to prostitute his pen or his pages to the advertiser, so long as he can secure the coveted revenue. So our journals are filled with articles and editorials containing covert advertisements of this and that remedy." He indicated that many of the proprietary medical houses would not advertise without a promise of reading notices and original articles in support of their remedies. The medical professions were beginning to divide periodicals into honest and dishonest publications: Dr. Foshay urged physicians to patronize the honest periodicals and to write to the editors of dishonest ones asking them to stop sending such periodicals to physicians.

The campaign was on in earnest. In the issue of The Journal for April 21, 1900 appeared the first of a series of articles designed to correct the abuses from advertising and patronizing unscientific pharmaceutic preparations. The article appears without indicated authorship; apparently it had the full support of the editor of The Journal. The series included analyses and criticisms of such products as Castoria and Syrup of Figs. These contributions were fighting articles; they were the first shots in the campaign that would lead eventually to the establishment of the Council on Pharmacy and Chemistry of the American Medical Association and to the development of a real science of pharmacology and therapeutics. The repercussions from this series of articles were acute. Pressure began to be made on the Board of Trustees of the Association by representatives of pharmaceutic industries.

The convention was now so large that difficulties were developing in the House of Delegates because it could never be clear just who was a delegate and who was not. A distinctive badge was given to the delegates and an attempt was made to seat them separately in the conventioin hall, but it was clear that issues of importance were sometimes being settled by the mob rather than by the delegates.

Dr. G. Frank Lydston began a series of articles on medicine as a business which was full of invective and satire, for which he was later to become famous.

ADDRESS BY W. W. KEEN

In his presidential address Dr. W. W. Keen noted that the Association now had 9,000 members and that there were 100,000 regular physicians in the United States. The Journal had reached a subscription list of 15,000, exceeded only by the *British Medical Journal* with 21,000. Dr. Keen was high in his praise of the quality of The Journal. He was disappointed with the Rush monument fund because it had now reached only $11,000: too small to go ahead and too large to go backward. He was anxious to see improvement in the membership of the Association. He stimulated the Scientific Exhibit. He urged that the editor and the Board of Trustees be given authority to publish only the papers from the sections that seemed suitable. Most of his address was devoted to the necessity for endowment of medical schools so that they might more nearly fulfil their educational functions. As a final recommendation in his address he proposed the establishment by the American Medical Association of a fund for scientific grants in aid of research. This proposal bore fruit. By 1946 the American Medical Association had given more than $1,000,000 of its funds for such purposes and had set aside as a permanent fund for research more than $2,000,000 additional.

THE ATLANTIC CITY SESSION

More than 2,000 physicians attended the Atlantic City session. The committee on arrangements recognized the excessive number of papers on the programs of the sections and recommended some type of restriction. Dr. George H. Simmons, secretary of the Association, presented in an orderly manner the various communications which had been received by his office. The proceedings were conducted formally. General Sternberg of the U. S. Army spoke to the idea that there need no longer be an *Index Medicus* because many of the journals were now printing good indexes. There was a motion by Dr. Ludvig Hektoen of Chicago for the formation of a new section on pathology and bacteriology. Dr. Donald Maclean of Detroit moved that reports of the treasurer and all secretaries be printed in advance of the time of the session so that time need not be taken in reading them. The name of the Section on State Medicine was changed to the Section on Hygiene and Sanitary Science. It was pointed out that the responsibility for accepting and rejecting papers was fully covered in the By-Laws.

CLEANING THE ADVERTISEMENTS

Toward the end of the session a resolution was offered by Drs. A. A. Eshner and Solomon Solis-Cohen. It read:

> *Resolved,* That the steps taken by the editor and trustees of The Journal of the American Medical Association looking toward the fulfilment of the expressed will of the Association, excluding from its columns advertisements of nostrums and secret preparations, be cordially approved, and that the editor and trustees be encouraged to continue in this course until the work is completed.

CENSORING THE SCIENTIFIC PAPERS

At the final session of this meeting a furor arose over an action by Dr. Denslow Lewis of Chicago. He had read a paper in Columbus on a gynecologic consideration of the sexual act. This paper had been refused publication in The Journal although it was included in the Transactions of the Section on Obstetrics and Diseases of Women. Two members of the publication committee of the section had rejected the manuscript, stating that they did so on legal grounds. Denslow Lewis had secured opinions from five attorneys in Chicago and insisted that his paper be published. There was much discussion, in which parliamentary procedure was cited pro and con. The President finally ruled that the whole discussion was out of order, and the resolution was referred to a committee for further report.

On the next day the Lewis paper was again the subject of a bitter battle. The Denslow Lewis paper had been read by the trustees and by the executive committee and all agreed that it should not be published; then the Association voted not to publish the paper.

Thus with the 1900 session the Scientific Exhibit became fully established. The editor of The Journal in retrospect feared that there were going to be too many sections. Today the number has grown to twenty. It was recognized that the exhibit should include not only pathologic specimens but also apparatus and other materials. Indeed it was pointed out that the aim should be to unify and correlate the scientific work at the meetings. The editor suggested that perhaps the sessions on pathology could be short so that its members might participate in the work of the other sections.

1901

ST. PAUL

The year 1900 marked a new century and gave opportunity for The Journal of the American Medical Association to review the progress of medicine in the United States for a hundred years. This statement from the leading editorial is prophetic:

> While assured that American medicine in the twentieth century will take an active part in the advancement of medical sciences, the sociologic relations of medicine in this country offer problems of great importance. There is need above all things for a greater public faith in the teachings and the advice of the medical profession in matters relating to hygiene and to the prevention of disease. Hygiene should dictate to legislators and courts of law and not economic interests alone. "Unfortunately on the human race there still weighs that fate by which both preventable diseases and premature deaths, as well as duration of life itself, essentially depend on economic institutions." There is hope that the twentieth century may witness great improvements as knowledge is disseminated and the mass of the people learn to place confidence in medical teaching.
>
> The medical college in the coming century will have to give more attention to the quality than the quantity of its output, if present signs are not misleading. Human nature will not change; there will still be deceivers and their followers, but this will only accentuate the demand for higher qualifications in our profession. The future of science is not in doubt; the world will not stop in its progress nor lose what it has gained, but the future of the medical profession is in its own hands and can only be assured by its living up to its higher ideals.

The quality of The Journal improved with almost every issue in the style of its presentation and in the character of its editing. Yet the action that was to unite the vast majority of the American medical profession into a single, closely knit unit based on a truly democratic system of representation had not yet been taken. The minds of many leaders were concentrated on the project but the 1901 reorganization was to be the mechanism by which medical solidarity would be brought about.

Following the meeting of 1900 a committee on organization, consisting of J. N. McCormack of Bowling Green, Ky., P. Maxwell Foshay of Cleveland and George H. Simmons, Chicago, was asked to report on organization. The committee proposed that a business section should be constituted to be known as the House of Delegates which should proportionately represent the state societies, according to their numerical strength and with the direct representation of one delegate from each scientific section. It was suggested that the ratio of representation for the state societies be fixed at one delegate to every 500 members. This proposal when adopted finally made the House of Delegates truly representative of the membership of the American Medical Association. The committee pointed out that by the means of committees this House of Delegates could deal exhaustively with all the large problems of state medicine. It would afford opportunity to every state to be heard in full, and free debate would be permitted. The states near the place of meeting would no longer wield a preponderant influence. The House of Delegates could work without interfering with the scientific work of the Association.

The committee had endeavored to provide every possible safeguard for maintaining this new organization as truly representative of the medical profession. Provision had been made against political campaigns, against perpetuation in office and against self election to office.

The committee requested every member of the Association to read carefully the proposed amendments to the Constitution and By-Laws. It prophesied that if the Association would give sanction to its recommendations the profession throughout the country in five years would be welded into a compact organization whose power to influence medicine would be almost unlimited and whose requests for desirable legislation would everywhere be met with that respect which the politician has for organized votes.

In the extensive report the committee analyzed the previous difficulties of the Association and the necessity for reorganization. It was particularly commendatory of the committee on nominations. The report suggested a common plan of organization for each of the state societies and a technic for securing members in county and state organizations. Indeed it went on to suggest forms for organization of such societies and duties for the state organizer.

THE ST. PAUL MEETING

When the Association assembled in St. Paul, June 4-7, 1901 the President, Dr. Charles A. L. Reed, said that by custom the President's address was restricted to a discussion of the affairs of the Association. He found that they were in excellent condition but he was especially pleased because The Journal of the Association had increased its circulation to 22,000 copies per week. Much of the business improvement had been brought about by the fact that the Association was now incorporated. He suggested that the articles of incorporation be confirmed by the Association at the St. Paul meeting. Dr. Reed was disturbed by the fact that The Journal had a circulation twice the membership of the organization. He felt that attention should be given to the handling of the surplus funds and he mentioned the desirability of securing and properly maintaining research and expanding The Journal. The final portion of his address was devoted to the reorganization, and he recommended the adoption of the new Constitution and By-Laws in their entirety. He pointed out that the committee on reorganization had wisely avoided any attempt to discuss the Principles of Ethics, but he suggested the establishment of a special committee to give consideration to that problem.

As the session opened, Dr. J. R. Pennington of Chicago presented to the Association a portrait of the founder, Dr. N. S. Davis.

Dr. George H. Simmons, secretary, read a report indicating that the membership was over 10,600, the largest increase in any year in the history of the Association.

The general executive committee had been successful in reducing the total number of papers read from 491 to 391. The highest number had been read in 1898, when there were 615 papers listed for presentation. This vast accumulation of papers to be read by title or presented only by listing in the program finally forced the adoption of essential corrective measures.

The Board of Trustees was able to report continuous improvement in The Journal and also in its advertising standards. All medicines advertised in the newspapers had been refused space in The Journal. As a result some products formerly advertised only in the public press were now being advertised only to physicians.

At a previous meeting of the Association the Constitution and By-Laws had been amended to provide for a standing committee known as the Committee on National Legislation to be appointed annually by the President. This committee was able to defeat the obnoxious bill against animal experimentation in the District of Columbia. It had also been able to aid in securing second class postage rates for The Journal of the American Medical Association, making a total saving of about $30,000 in postage.

NATIONAL LEGISLATION

Attempts were under way to develop uniform medical legislation on the basis of a uniform medical education. The distinguished committee, which included Drs. H. L. E. Johnson, William H. Welch and William L. Rodman, recommended an annual conference in Washington of representatives of state legislative committees to consider general trends in both state and national legislation relating to the medical profession. Such a conference had been held in Washington in February of 1901 with a good representation from many of the states. They had been principally concerned with the army reorganization bill and with the duties of the Marine Hospital Service. They had also been concerned with perfecting an organization which would enable the national legislative committee to cooperate fully with the state committees.

The Rush monument fund had now reached $11,941.88.

A significant occurrence at this meeting of the Association was the presentation of Miss Susan B. Anthony, who spoke briefly on the subject of regulating vice in Manila, Hawaii and Porto Rico. She was readily seconded by Rev. Anna Shaw.

Following the address of the President, Dr. Charles A. L. Reed, the general executive committee, which acted as a reference committee for the session, urged the appointment of a committee of three to revise the Code of Ethics and with instructions to report at the next annual session of the Association. This was, however, laid on the table; apparently there was in the meeting a group which did not wish to have this question raised.

The Association voted a resolution of profound appreciation of the generous gift of John D. Rockefeller, who had given $200,000 for medical research, under the able chairmanship of William H. Welch.

The facts about the reorganization are so fundamental to the progress of the American Medical Association that I requested Dr. George H. Simmons to write the story. He prepared it in 1933, nine years after he had resigned as editor of The Journal. The article follows:

COMMITTEE CREATED

The annual meeting of the Association for 1900 was held in Atlantic City, June 6 to 10. At the second General Meeting the following resolutions, no preamble, were introduced by Dr. D. R. Brower, Chicago, a member of the General Executive Committee:

> *Resolved,* That a committee be appointed by the Association on the organization of the profession throughout the United States to cooperate with the Committee on National Legislation; this committee to consist of one member from each state and territory represented in the Association.
>
> *Resolved,* That a committee of three be appointed by the President to prepare plans in detail for such committee on organization; to enter into correspondence with officers of the various state societies, and to take such action in the premises as it may think advisable, and that the Trustees be requested to appropriate a sum not exceeding $150 for the necessary expenses of the committee.

According to the usual procedure, the resolutions were referred to the General Executive Committee. The following day they were referred back with recommendations for adoption. By motion, a representative was added to the large committee—referred to hereafter as the States' Committee—from the Medical Department of the Army, of the Navy, of the Marine Hospital Service and from the Bureau of Animal Industry, respectively.

The Committee on National Legislation, mentioned in the first resolution, was a standing committee on national—congressional—legislation and would not be concerned with the subject matter in the slightest degree.

There were two purposes in view in creating the States' Committee. First, to represent the state and territorial associations, each of which would be asked to appoint a member. Any plan of organization to include the whole country would require the approval, and cooperation in carrying it out, of all the state organizations. This cooperation would be absolutely essential to a successful outcome: hence the main reason for the States' Committee.

Second, the States' Committee would make a large and representative group to which the Committee on Reorganization would make its report, in the first instance at least, rather than to a General Meeting. It proved an ideal arrangement.

COMMITTEE APPOINTED

The Committee on Reorganization was appointed by the newly elected President, Dr. C. A. L. Reed, and consisted of Dr. W. W. Keen, Philadelphia, the retiring President; Dr. J. N. McCormack, Bowling Green, executive officer of the Kentucky State Board of Health, and Dr. George H. Simmons, Chicago. Presumably Dr. Keen was appointed because of his great popularity (he was loved by all who knew him); his membership on the committee therefore would add confidence in it and its work. He later resigned (the committee was not yet organized) because his professional work made it impossible for him to give to the committee the time and attention required. Dr. P. Maxwell Foshay, Cleveland, secretary of the Ohio State Medical Association, was appointed in his place. As now constituted, each member of the small committee was, or had been, officially connected with a state medical association.

FIRST MEETING OF THE COMMITTEE ON REORGANIZATION

The first meeting of the committee was held in Chicago in October (1900) and organized by electing Dr. J. N. McCormack chairman and Dr. George H. Simmons secretary. It was in session two days, during which it outlined the whole scheme of organization which it proposed to recommend and left the working out of the details to future meetings and to correspondence.

In addition to two or three meetings in Chicago, the committee, after the plan of reorganization had been pretty thoroughly worked out, held one meeting in Cincinnati, one in St. Louis and one in Chicago; to these meetings local men who might be interested were invited for conference. These conference meetings were helpful in many ways. A brief statement on some of the subjects the committee had to consider may be of interest.

PLAN OF ORGANIZATION

The general plan of organization was, of course, the first matter taken up by the committee. The following is an outline of the plan tentatively adopted at its first meeting:

The unit of the organization to be the local society, preferably the county; membership in the county society to carry with it membership in the state association; the state association to create a legislative body or branch to be composed of delegates elected by the component (county) societies. The American Medical Association likewise would create a legislative body, its members to be elected by the legislative bodies of the state associations and one by each of the sections; also appointed representatives of the government services. There was nothing unique—nothing original—in the general scheme; it was in use in its essentials by national, religious and social organizations, by fraternal and secret societies, and, at that time, by the United States Senate. There was no other plan on which the medical profession of the United States could be organized if it was to represent the profession of the whole country.

The Unit.—What shall constitute the unit of the organization? Naturally, the ideal would be the county. But in thinly populated states there were counties without a sufficient number of physicians to constitute a society. This problem could be solved by providing for component multiple county societies.

The opposite condition would be a county containing a large city, so large, geographically and in population, that one component society would not meet the required conditions. Boston, New York, Philadelphia and Chicago were considered.

Massachusetts has its districts, not counties; Boston included two of such districts, each with its district society.

New York City covered four counties: four component societies would be satisfactory; Philadelphia was geographically small and one component society would probably be satisfactory.

Chicago (Cook County) was a more difficult problem. Cook County is large geographically and even then was thickly populated. The committee recommended that subdivision of such counties should be made.[1]

Maximum Number of Members in House of Delegates.—This should be sufficiently large to make proportional representation for the thickly populated states, but no larger. Investigation showed that, based on the proportion of one delegate to each 500 members of a constituent association, plus one representative from each of the sections and from each of the three government services, would make the House consist of about 145 members. This would give proportional representation. One hundred and fifty as a maximum was recommended and adopted.

Presiding Officer for the House of Delegates.—It was the unanimous opinion of the committee that the House of Delegates should have its own chairman, one who would be selected for his ability to preside rather than for his scientific achievements or popularity. The office should be more or less permanent; the one selected would be more likely to master parliamentary rules than would be the case if one had to preside for one year only. Then there are certain lines of business that are more or less continuous, and the presiding officer should have knowledge of such matters.

However, while the committee had not changed its views, it concluded that the question was a delicate one and might well be left to the members of the House to decide for themselves.

While acting on the rule it had adopted, that is, to make only such modifications of the By-Laws as were absolutely necessary for working out the essentials of the plan, it is probable that the committee carried this policy too far in some matters, possibly in this.[2] For instance, the paragraph in the old constitution on "Permanent Members" was retained although it had no meaning in the new. The articles on "Funds" was left intact, one clause of which read "an equal assessment of not more than ten dollars annually on each of the permanent members." The "ten dollars" caused vigorous objections in the States' Committee Conference until it was explained that it had been in the old constitution for as long as the records ran. Even "four vice presidents" were still provided for; it so remained until 1920, when the By-Law was changed to provide for one vice president. The By-Laws also contained incongruities because of the decision to make only such changes as were absolutely essential. As was expected, these incongruities were eliminated as the years passed.

THE REPORTS

The preparation of the preliminary report was allotted to Drs. J. N. McCormack and G. H. Simmons; to Dr. Foshay was assigned the task of suggesting the necessary modifications that should be made in the By-Laws. This separate work was done between meetings, but all matters were later thoroughly discussed by the committee in session. There were two reports: (1) the preliminary report and (2) the official report.

The former was the more important and consisted of two parts, an explanatory preface or introduction, and the "argument."

The preface fully outlined the changes proposed and specifically detailed the more important ones. It was a summary such as would give one a clear idea of what changes were proposed and the results expected, if and when this proposed reorganization became a fact.

---

[1] After reorganization a special committee recommended that the Chicago (Cook County) Medical Society should be a Councilor District; that each branch should be a component unit of the state association. This plan was successfully carried out, with this important exception: as component societies, each branch would be entitled to send representatives to the House of Delegates of the state society. This right the branches do not have. The delegates of the state body are elected by the Council (the business body) of the Chicago Medical Society. This arrangement is perfect for the latter but not for the state society.

[2] In a few years a feeling had developed that a permanent presiding officer was desirable. Dr. Happel, then chairman of the Board of Trustees, introduced an amendment to the By-Laws to provide for a chairman for the House of Delegates. It caused resentment, and the chairman of the Board of Trustees was hissed; the proposal was regarded as an insult to the President of the Association, then presiding. It was not until 1916 that a By-Law was passed creating the office of chairman of the House of Delegates. Dr. Hubert Work was elected to the office. In 1918 the word "chairman" was changed to "speaker." Dr. Work resigned in 1920 and became President. He was succeeded by Dr. Dwight Murray, New York, who presided one year (1921) and was reelected but died the following October. Dr. Frederick C. Warnshuis was elected speaker in 1922 and has been reelected each year since.

The "argument" was an exhaustive review of the conditions in the Association, past and present, that made reorganization necessary; it outlined the benefits that would result from such a reorganization as recommended.

The preliminary report in pamphlet form occupied forty-eight pages, six of which were required by the introductory preface. The official report was submitted first to the States' Committee Conference and later presented to the General Meeting of the Association; with it was submitted the revised Constitution and By-Laws

PRELIMINARY REPORT DISTRIBUTED

The Preliminary Report was complete and in form for distribution in April 1901. A copy was sent to each member of the States' Committee, with a special typewritten letter asking for criticisms and suggestions. Included in the letter was a call for the conference to be held in St. Paul, June 3. Also with a similar letter copies were sent to the president of each state and territorial association, to the members of the General Executive Committee, to officers of the Association and to about 400 physicians located in various parts of the country, selected as far as possible from physicians known to be interested in the welfare of the Association. In all letters a request was made for criticisms and comments. A stamped return addressed envelop was an enclosure; also an invitation to attend the States' Committee Conference. Altogether, *approximately, 500 letters were sent.*

The number of replies received indicated a decided interest in the subject; as I recall, approximately 80 per cent acknowledged receipt of the preliminary report. Before me is a bundle of about 100 of these letters. A few are little more than an acknowledgment of receipt of the preliminary report; some are long: one written in long hand takes ten large letter-size sheets; the longest, however, consists of seven such sheets, typewritten, single space and small type face—a size common at that time.

The general tone of each of these and of a few other letters is a fear of what would happen if the plan proposed was adopted Practically all contain constructive criticisms and suggestions, many of which were adopted A comparison of the recommendations in the preliminary report with the Constitution and By-Laws as submitted and finally adopted will show this. The number of letters that may be regarded as absolutely opposed is small and practically without exception are from the older, faithful members—"wheel-horses," using the term in its best sense—of the Association.

One letter I quote—not that it indicates definite opposition, but because it is from the "Father of the Association," a man who did more than any other to improve conditions and to bring about reforms.

Chicago, Ill, May 8, 1901
65 Randolph Street

To George H. Simmons, M D

Dear Doctor —On referring to the report that I made as chairman of a committee on revision of the Constitution of the American Medical Association *in 1887, and the action thereon* by the Association at the meetings in 1887-88 89, I find that *all* of the *amendments* both to the Constitution and to the By Laws that were recommended in my report were fully considered and *adopted,* except that *one* relating to the formation of a general committee of two members from each state, territory, Army Navy and Marine Hospital Service to take the place of the nominating committee and serve as a permanent general committee, which was finally fully discussed and *rejected* at the meeting at Newport, 1889 And I still think if such a *council* or *standing general committee* as proposed in that report of 1887 was adopted to take the place of both the *present business committee* and the nominating committee, it would be more simple and efficient than the scheme outlined in the report you sent to me.

Yours truly,
N. S Davis

The report Dr. Davis mentions is the one to which reference was made to the effect that had it been adopted it would have made unnecessary *the radical reorganization proposed.*

The preliminary report was given its greatest publicity when it was published in The Journal of the American Medical Association, May 25, 1901.

THE STATES' COMMITTEE CONFERENCE

The States' Committee met at St. Paul, June 3, 1901, to act on the recommendations of the Committee on Reorganization, and on the revised Constitution and By-Laws. The conference was a large and representative gathering. Two sessions, morning and afternoon, were held.

The conference was called to order by Dr. J. N. McCormack, chairman of the Committee on Reorganization. Dr. H. O. Walker, Michigan, was elected chairman and Dr. George N. Kreider, *Illinois,* secretary.

As all had received a copy of the preliminary report, they knew the subject to be acted on by the conference. The pamphlet containing the official report and the revised Constitution and By-Laws was distributed. The official report was then read, and *the meeting* took up, section by section, the revised Constitution and By-Laws. Three or four minor modifications were made, but there was one which could not be regarded as "minor." As has already been stated, the committee recommended that each section should be entitled to one delegate; the conference changed this to two delegates. The idea that the sections still constituted the American Medical Association remained in the minds of the majority. Two years later the By-Laws was changed back to the number recommended by the committee, one delegate from each section.

No organic laws were ever more carefully scrutinized than were the Constitution and By-Laws of the American Medical Association passed on at this conference.[3]

REPORT PRESENTED TO THE GENERAL MEETING

The next morning the following official report was presented to the General Meeting by Dr. J. N. McCormack:

"Officers and Members of the American Medical Association:

"We, your Committee on Reorganization, respectfully submit *the following:*

"We have keenly felt from the first the magnitude of the task set for us, but in all the months of exacting labor we have been spurred on by the hope that our work would, if wisely performed, and if accepted by you, mark the dawn of a new era in the history of American medicine. After full consideration of the problems before us we early reached the conclusion that it would be useless at this late date to suggest the adoption of either half-way or compromise measures, and, therefore, we have prepared and now submit a completely revised Constitution and By-Laws designed to federate all the state organizations into this Association, to foster scientific medicine and to make the medical profession a power in the social and political life of the republic.

"In a recent issue of The Journal we submitted for your consideration a full outline of the changes proposed and, in an exhaustive manner, presented the reasons for our recommendations. We earnestly request that every member of the Association, before passing judgment, carefully consider all the facts and *arguments presented.* Such *examination will* make it clear that we have been conservative, suggesting only such changes in the organic laws as are essential to the accomplishment of the high purpose for which the Association was organized.

---

[3] The official copy of the pamphlet containing the Constitution and By Laws, in which were written the modifications made during the conference, has written on its title page "Original Copy of Report as handed in by Dr. Walker, Chairman Joint Committee—Wm. Whitford" (Whitford was for many years official reporter to the American Medical Association) Attached to this pamphlet is a sheet bearing the signature of members *of the States' Committee. It is headed* "We the undersigned have examined, and hereby endorse and approve of the above revised Constitution for the American Medical Association." The following are the signatures.

W. G. Harrison, Alabama
Gould A Shelton, Connecticut
W. N Fisher, District of Columbia
John Palmer Jr., Delaware
W. W. Grant, Colorado
A W. Alvord, Michigan
Henry O Marcy, Massachusetts
Henry D. Didama, New York
George Cook, New Hampshire
Philip Marvel, New Jersey
George N. Kreider, Illinois
G. W. McCaskey, Indiana
R. E Conniff, Iowa
J. A Crook, Tennessee
A H Thayer, West Virginia
J. W. Aird, Utah
George Tully Vaughan, Marine Hospital Service
H M. McClanahan, Nebraska
A *Garcelon, Maine*
R. Harvey Reed, Wyoming
J. H. Pritchard, Wisconsin
J. D Griffith, Missouri
W. J Means, Ohio
Charles Richard, U. S Army
Joseph M. Mathews, Kentucky
J A. Dibrell, Arkansas
John L. Wills, California
J. L Catterson, Washington
John A Wyeth, New York
G R Dean, North Carolina

"It will be seen that we have left the Code of Ethics, based on the original resolution of adoption, undisturbed and still in force. We have carefully preserved the membership of all those now in the Association and have jealously guarded the rights and privileges of each state organization now in affiliation with this body.

"In accordance with your instructions we have also submitted to the larger committee, composed of one member from each state, a detailed scheme for the organization or reorganization of state and county societies, in harmony with, and in completion of the general plan, in which we ask your concurrence.

"The various portions of the scheme of organization proposed are interdependent and should be permitted to stand or fall together. During the time devoted to the preparation of the report, we have considered the various questions in detail and have rejected many propositions that we at first thought worthy of adoption, so that we feel that no amendment can be proposed from the floor which has not already been fully considered. We appreciate the fact that some of the details proposed are to a certain extent experimental, and their true value can only be determined by the test of experience.

"As all the changes outlined, and the reasons for them, have been fully placed before you, no discussion of any part of them will be attempted here, the Constitution and By-Laws clear and distinct in every provision, being submitted as our unanimous report.

"Respectfully,
"J. N. MCCORMACK.
"P. MAXWELL FOSHAY.
"GEORGE H. SIMMONS.
"COMMITTEE ON REORGANIZATION."

It was at once referred to a joint committee composed of the General Executive Committee and the States' Committee. (This action was following the usual custom although it was referring the matter back to the same group who had acted on it the day before.) The next day this joint committee reported to the General Meeting recommending the adoption of the report of the Committee on Reorganization and the revised Constitution and By-Laws. The report was adopted, with practically no discussion, and the new order went into effect on the adjournment of the St. Paul meeting.

As this was only the first step in the reorganization, the Committee on Reorganization was ordered to continue its work to a full completion of the scheme.

"It is interesting to note that this radical change in the organic laws of the American Medical Association was made without being subjected to a discussion—worthy of the name—in a General Meeting. There was no reason, of course, for a discussion; the whole matter had been thoroughly gone over by a group which the General Meeting regarded as competent to advise. Further, those who were in the States' Committee Conference constituted a goodly portion of the members present at the General Meeting, at which the foregoing action was taken.

• • • • • • •

What happened when the General Meeting—the supreme legislative body of the Association—adopted the Report of the Committee on Reorganization and approved the Constitution and By-Laws suggested by the committee and endorsed by the States' Committee? By this action the General Meeting surrendered its legislative functions to the newly created House of Delegates; also its claim to be the representative body of the medical profession of the United States—in a word, the old organization, in its completeness, went out of existence. As Dr. J. N. McCormack put it, "It will therefore be seen that historically the House of Delegates is the legitimate successor and direct outgrowth of the delegated body known as the American Medical Association."

But the annual meeting of the American Medical Association was held the following year (Saratoga, N. Y., June 10-13, 1902) apparently the same as before; there was the usual Opening General Meeting with the same formalities of welcoming addresses and responses, followed by the usual presidential address; likewise the other General Meetings were held as usual, at which the orations on surgery, medicine and so on were delivered. Yet there was a difference; there was no business transacted at the General Meetings. That was the only change. This was pleasing to those whose interest was chiefly in scientific medicine. On the other hand, there were some—particularly among the older members—who regretted the innovation.

Exactly as in former years the sections met day by day and carried out their respective programs. The only reminder of a change that the members might notice was that each section was required to elect a representative to the House of Delegates.

There was a change in the registration bureau. No new members were registered as delegates from "Affiliated Societies." Those who became members (Fellows of the Scientific Assembly) that year, and thereafter, did so under the old formula, "Members by Application."

Thus it will be seen that while, as Dr. McCormack said, the House of Delegates succeeded "the delegated body known as 'the American Medical Association,' the Association, as a scientific body, continued to exist and to function essentially as before; it so continues as that branch of the Association known as 'the Scientific Assembly of the American Medical Association. . . .'"

Clinical Notes, Suggestions and New Instruments

STREPTOMYCIN THERAPY IN PYLETHROMBOPHLEBITIS

J. H. WISHART, M.D.
and
L. J. PETERSON, M.D.
Minneapolis

Pylephlebitis is a thrombophlebitis involving the venous channels of the portal system. Subsequent development of multiple abscesses of the liver results from septic emboli or from progression of the inflammatory process. The mortality rate is extremely high. Acute suppurative appendicitis is the most frequent antecedent lesion, and it is this association with which we are concerned in the present paper.

Ochsner, DeBakey and Murray,[1] in a review of the literature, pointed out that the first report of appendicitis complicated by multiple abscesses of the liver is generally conceded to Waller, quoted by Laison.[2] Other early reports include that of Reginald Fitz[3] in his classic contribution in 1886.

The incidence of portal thrombophlebitis and hepatic abscess following appendicitis varies from 0.10 per cent to 0.50 per cent. In Ochsner's[1] series of 5,293 cases of acute appendicitis during the ten year period 1928 to 1937, inclusive, there were 5 cases complicated by abscess of the liver, an incidence of 0.09 per cent. He cited also a collected series of 68,198 cases of appendicitis in which there were 247 cases with these complications, an incidence of 0.36 per cent. Petrén[4] stated that abscess of the liver or suppurative pylephlebitis of the portal vein occurred in from 0.3 to 0.4 per cent of all cases of appendicitis, and that these complications occur in at least 5 per cent of all fatal cases of appendicitis. Hawkes[5] reported 1,463 cases of appendicitis with 12 cases of pylephlebitis over a ten year period, or an incidence of 0.82 per cent.

Pylephlebitis is usually a complication of a severe inflammation of the appendix, most frequently gangrenous. The organisms most frequently involved are streptococci, Escherichia

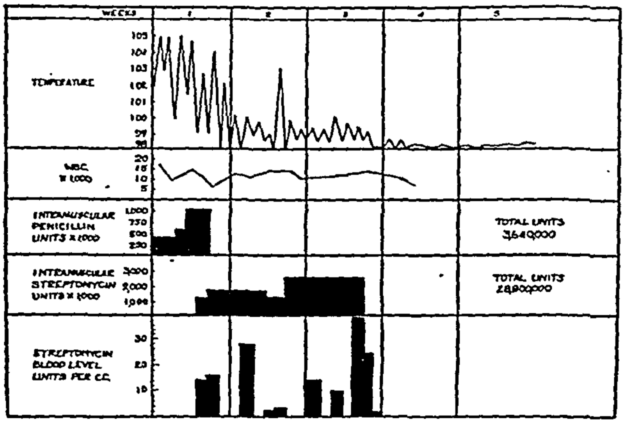
coli and staphylococci, or a combination of these. A thrombophlebitis of the intramural vessels of the appendix occurs, and this may progress to involve the appendical veins in the mesoappendix, thence to the ileocolic, superior mesenteric and portal veins. In other instances small septic emboli may become detached from a thrombus localized in the vessels near the involved appendix and reach the liver through the venous radicles of the portal system. Thus multiple hepatic abscesses may develop.

The symptoms of phlebitis complicating acute suppurative appendicitis are those of the antecedent appendicitis followed by the sudden onset of chills and an accompanying high fever out of proportion to that anticipated from the local inflammatory lesion in the appendix. The elevation of temperature may spike sharply with the chills, and profuse sweating may occur. Other symptoms of pylephlebitis with hepatic abscesses include abdominal pain, anorexia, malaise, asthenia and loss of weight. Jaundice may appear as a late manifestation. Ascites occurs in some cases. The leukocytosis in pylephlebitis is usually well defined with a relative increase in the polymorphonuclear cells. Blood cultures are most frequently negative.

Surgical treatment of pylephlebitis consists in ligation of the involved veins above the level of the thrombosis to prevent septic emboli from reaching the liver. Wilms[6] in 1909 advised ligation of the veins at the ileocecal angle and reported a successful case. Subsequently, numerous investigators have cited cases of the disease treated by ligation of veins at various levels. Hawkes[5] in 1938 recommended ligation of the ileocolic vein at the point where it joins the ascending colic vein. He cited 24 instances with ligation at various levels with 8 deaths, or a 33 per cent mortality rate.



Summary of data in case of pylethrombophlebitis.

Chemotherapy has been used successfully in the treatment of pylephlebitis associated with acute appendicitis. In 1938 Ottenberg and Berck[7] reported 2 cases of the disease treated with sulfanilamide with subsequent recovery. Murray and Donelson[8] have reported a case in which treatment with sulfathiazole resulted in cure. These authors considered significant the fact that the infection did not progress to suppuration following chemotherapy.

Antibiotic therapy has been used recently with success. Gamm[9] in 1945 treated a case of pylephlebitis with penicillin, and the patient recovered completely. Wilensky[10] in 1945 used large doses of penicillin and sulfadiazine in treating a case of pylephlebitis associated with acute suppurative appendicitis. Recovery ensued.

The course of pylephlebitis with the development of hepatic abscesses is usually decidedly protracted. Data on cases of the disease with multiple abscesses of the liver show an exceedingly high mortality rate. Surgical drainage is advisable when a solitary accessible lesion can be demonstrated. Cures resulting from chemotherapy have in many instances had a lengthy course because of the development of hepatic abscesses. When involvement of the liver can be prevented, one may hope for an early recovery.

REPORT OF CASE

History of Present Illness.—A white man aged 28 was admitted to the hospital at 11:30 p. m. July 30, 1946. The onset of the present illness was July 28, two days prior to admission, with a history of generalized cramping abdominal pain, recurrent chills and fever and headache. These symptoms were attended with nausea but not with vomiting or diarrhea. On one occasion he manually forced himself to vomit in an attempt to relieve the pain, which was severe enough to keep him awake most of the day and night. Two days after the onset of symptoms, the diffuse abdominal pain gradually localized in the right lower quadrant, and changed in character from an intermittent cramping pain to an almost steady, severe pain. The patient stated that on the day prior to admission his temperature was 99.6 F. On the morning of the day of admission his temperature was 102 F., and he had a frank chill in the afternoon and another in the evening. His temperature reached 105 F. during the latter episode. He then called his family physician, who sent him into the hospital.

Past Medical History.—The patient had spent seven months in the Philippines in military service. This tour of duty terminated in February, 1946 with no history of tropical disease or other serious illnesses. Systemic review revealed essentially normal conditions. There was no history of rheumatic fever. He had had the usual childhood diseases. His present occupation was that of a bottler in a brewery.

Physical Examination.—On admission to the hospital the patient weighed 135 pounds (61.2 Kg.) and appeared acutely ill. He was perspiring profusely and complained of severe abdominal pain. His temperature was 102 F., his respiratory rate 28 and his pulse rate 86. Examination of his head, eyes, ears, nose and throat revealed essentially normal conditions.

Chest: His chest showed equal excursion and expansion. Neither rales nor evidence of impaired resonance was evident on auscultation. The heart was not enlarged to percussion. The blood pressure was 134 systolic and 84 diastolic. The rhythm was regular; the heart tones were of good quality and equal intensity; murmurs were not heard.

Abdomen: The abdomen was scaphoid in type and not distended. There was pronounced tenderness to deep palpation in the right lower quadrant with associated spasm of the right rectus abdominis muscle. The liver and spleen were not palpable. There was no tenderness to percussion over either costovertebral angle posteriorly. Rectal examination revealed decided tenderness high on the right side. There was no evidence of petechiae. The lymph nodes were not enlarged. Neurologic examination was noncontributory.

Laboratory Data.—*Examination of the Blood*: The total white blood cell count was 15,600 with a differential count of polymorphonuclear leukocytes 87 per cent, lymphocytes 8 per cent and monocytes 5 per cent. Urinalysis: The urine was straw colored, the specific gravity was 1.025, and the albumin, sugar and microscopic tests were negative. Malaria Smears: Parasites were not found in malaria smears. Stool examinations were negative for ova and parasites.

On the basis of the preceding history, physical examination and laboratory data, a diagnosis of acute appendicitis was made.

Hospital Course.—The patient was operated on two hours subsequent to admission. The abdomen was opened through a McBurney type muscle-splitting incision. Free fluid was not encountered. The appendix was found lying retrocecally with considerable thickening and edema of the surrounding tissues. The appendix was congested and covered with a fibrinous exudate. Because of its retrocecal position and highly inflammatory state, the appendix was removed in a retrograde manner. The stump was not inverted; the abdominal cavity was

10. Wilensky, A. O.: Pylephlebitis Under Penicillin and Sulfadiazine Therapy, New York State J. Med. **45**: 2082 (Oct. 1) 1945.

not drained. The abdomen was closed in layers with interrupted silk sutures.

The postoperative clinical course was unchanged from that preoperatively. The spiking high fever with recurring chills continued with temperature elevations to 105 F. daily (see the accompanying chart). Repeated blood smears were negative for malaria organisms. Penicillin therapy was instituted on the day following surgical intervention, 40,000 units being administered intramuscularly every three hours. The dosage of penicillin was increased to 50,000 units every two hours and finally to 100,000 units every two hours without apparent effect on the clinical course. Penicillin therapy was discontinued on the fifth day postoperatively.

Blood cultures were taken on the first, second, third and twelfth days after the surgical operation. The second and third blood cultures were positive for hemolytic Staphylococcus aureus which were coagulase positive. This organism was sensitive to 0.02 unit of streptomycin per cubic centimeter and 0.1 unit of penicillin per cubic centimeter. Inasmuch as these two blood cultures were taken while the patient was receiving large doses of penicillin (the organism hemolytic Staph. aureus being sensitive to 0.1 unit of penicillin per cubic centimeter), and since the pour plates were negative, it is possible that the organisms recovered on these two occasions were contaminants. The other two blood cultures were negative. On the basis of the postoperative clinical course and the laboratory observations, a diagnosis of pylethrombophlebitis was made, and streptomycin was considered the drug of choice.

On the third day postoperatively the lower end of the incision was opened and approximately 3 ounces (85 cc.) of purulent material was evacuated from a subcutaneous wound abscess. Culture of this exudate revealed Esch. coli. A streptomycin sensitivity test revealed that the Esch. coli was sensitive to 1 unit of streptomycin per cubic centimeter and to 5 units of penicillin per cubic centimeter.

The patient was started on streptomycin therapy August 4, the fourth postoperative day. He was given 0.4 Gm. of the drug every six hours for six days, 0.3 Gm. every six hours for the next two days, then 0.4 Gm. every four hours for the duration of the treatment. A total of 28.8 Gm. of streptomycin, or 28,800,000 units, was administered. (See the chart for the streptomycin blood levels and the coincident clinical response.) Streptomycin blood levels were taken two hours after one of the morning injections. There was one episode of chill and temperature elevation while the patient was receiving 0.3 Gm. every six hours for two days. Streptomycin blood levels on these two days dropped to 2 and 3 units, respectively. The final streptomycin blood level was taken twenty-four hours after the last injection. In twenty-four hours it had dropped from 25 units to 1.2 units per cubic centimeter of blood.

Throughout the course of streptomycin therapy, daily laboratory work was performed, which included hemoglobin determination, red blood cell count, white blood cell count, differential count and urinalysis. The red blood count was normal throughout the course of the disease. The white blood cell count ranged from 18,000 at the height of the disease to 8,000 prior to discharge. At no time was there any significant change in the differential count other than a relative increase in the percentage of polymorphonuclear leukocytes. Urinalyses were normal throughout the course of the disease. On August 3 the total bilirubin was 0.6 mg.; on August 7 it was 1.0 mg. per hundred cubic centimeters. On the same day the sulfobromophthalein retention was 0.8 mg. per hundred cubic centimeters. The cephalin cholesterol flocculation test was 3 plus in twenty-four hours and 4 plus in forty-eight hours. On August 15 the cephalin cholesterol flocculation test was 1 plus on both the twenty-four and the forty-eight hour determination.

The patient became asymptomatic six days before streptomycin therapy was discontinued and has remained so since then. At the time of writing it is five weeks since he has received any medicaments. At no time while on streptomycin therapy did he receive any other medicament that in any way could confuse the results obtained by streptomycin therapy. He at no time exhibited any sensitivity to the drug.

Operative Tissue Examination Report.—The specimen, examined by Dr. J. Y. Clarke Jr. of the Department of Pathology, consisted of an appendix 7 cm. in length. The serosal surface was congested and covered with a fibrinous exudate. There was a fibrous operculum over the distal end of the appendix. Microscopic sections revealed that the lumen of the appendix contained a hemorrhagic purulent exudate. The mucous membrane had been completely destroyed. There was extensive necrosis of the muscularis and of the connective tissues of the appendical wall. One of the larger veins of the subserosa was filled with neutrophils and partially hemolyzed red blood cells. The walls of the veins were infiltrated with neutrophils. Other large veins of the serosa and mesoappendix showed an infiltration of the neutrophils into the adventitia.

SUMMARY

A young man made a dramatic recovery in an extremely short time from pylethrombophlebitis, a disease that in the past has been almost uniformly fatal.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

HOME DIATHERMY

From time to time in the past ten to fifteen years, efforts have been made to promote the buying of home diathermy apparatus directly by the public. At first sight this may seem reasonable because the application of heat often brings relief from pain and is recognized as beneficial in many conditions. It is also argued that diathermy is much more convenient, and at times much more effective, than the hot water bottle and similar devices, and that modern improvements in the diathermy equipment might obviate such objections as the danger of burns to the patient and interference with radio equipment in the vicinity. Nevertheless, it has been necessary for the medical profession to oppose the general sale of diathermy equipment. The reasons for this policy need occasionally to be set forth.

Medical diathermy is the therapeutic use of heat generated within the tissues of the body by the high frequency current actually passing through the tissues. Such currents are applied by one of three methods: (1) conventional, long wave diathermy, in which large metal electrodes are applied directly to the surface of the body and constitute the terminals whereby the rapidly alternating current enters and leaves the body, (2) short wave diathermy, in which the large, flat electrodes are air spaced or insulated, do not make actual contact with the skin and simply induce the electrical currents in the body, and (3) short wave diathermy, in which a cable is so placed that the rapidly fluctuating electromagnetic field surrounding it affects the body of the patient. As is well known, all three types of diathermy apparatus can be made powerful enough to cook food and pop corn and, of course, can coagulate and kill tissues; when carefully controlled, they can be used to induce high fevers for the treatment of neurosyphilis and similar conditions. It is a truism that any material or device which is utterly incapable of harm is likely also to be ineffective therapeutically. Diathermy apparatus, if strong enough to be effective, should be employed with due caution as a medical instrument to treat specific conditions diagnosed by physicians.

It cannot be assumed that all tissues will be heated equally by diathermy. In some parts of the body there is a very active flow of blood through the capillary vessels, so that the tissues are cooled just as the engine of an automobile is cooled by the circulation of water through the radiator. Other parts of the body have a less active blood supply, and there are a few, like the lens of the eye, that have no blood vessels at all. Such parts are unable to cool themselves when heat is generated inside them as it is in diathermy, even when the tissues are normal. When tissues are diseased, the situation is generally worse, for the foot of a patient with arteriosclerosis, or the interior of a large tumor within the abdomen, may have a very poor blood flow. Such tissues can become overheated. Injuries to nerves or to the spinal cord often impair the sense of temperature in related parts of the body, so that the patient may be unable to tell when a paralyzed limb is overheated. Evidently there are many possibilities for localized damage by diathermy. In addition, however, the production of artificial fever by diathermy brings up the possibility of generalized damage, for there are cases on record in which the temperature went above the levels which nature seems to set for natural fevers, so that death resulted from heat prostration.

It is sometimes necessary to remind patients of the general objections to self medication or self treatment. A physician places at the disposal of his patient the wealth of accumulated human experience represented in his medical education and in his current reading of medical literature, as well as his own personal experience in medical practice. The physician is able to prescribe effective remedies when they are known, is able to protect his patient from supposed remedies that are potentially harmful and, finally, saves his patient valuable time and money by discouraging remedies known to be useless in his particular case. It is, in other words, part of his function to speak out when he sees money spent in dangerous or even ineffective ways. The medical profession obviously cannot encourage the expenditure of substantial sums by patients who wish to experiment privately with new devices instead of getting information from experts. It is also true that the advancement of medical knowledge is retarded if experimentation is done by patients and if the results, favorable or unfavorable, are left unpublished; the medical ideal is to carry out the testing of new procedures under conditions which permit the systematic assembling and publication of results.

There are numerous contraindications to diathermy that require a knowledge of medicine. Some widely disseminated advertising has failed to mention the dangers encountered in its use. Some firms have even recommended the use of home diathermy for conditions in which medical experience has shown it to be specifically contraindicated; for instance, acute nondraining cellulitis, acute infectious arthritis, any condition with a tendency to hemorrhage such as gastric ulcers, and conditions in which the temperature sense is lost, as in nerve injuries. Diathermy must also not be applied to the abdomen and pelvis in pregnancy or during menstruation and should not be applied to most types of tumors; yet some advertising has encouraged such misuse. The cautions against misuse are based on numerous very unfortunate mishaps known to physicians to have occurred during the early days of medical diathermy, and it is evident that the dangers of using a diathermy apparatus without explicit medical supervision should be emphasized. The end result of such "slot machine diathermy" may be not only severe physical injury but also the cause of lawsuits.

Realizing the therapeutic limitations of diathermy apparatus, the Federal Trade Commission has ordered several companies to cease from disseminating advertisements which represent directly, or through implication, that the respondent's diathermy apparatus may be easily and safely used in the home. The Council on Physical Medicine of the American Medical Association has repeatedly refused to accept home diathermy machines "for inclusion in its list of acceptable devices."

Under special circumstances it is possible that a physician will wish to recommend the renting of a diathermy machine for daily use in the home of a patient whose condition has been accurately diagnosed and whose treatment will be entrusted to some person with the requisite intelligence and training. It is apparent, however, that the indiscriminate use of diathermy equipment in the home is bad and that such devices should not be advertised as "recommended by the medical profession" when they are to be sold to the public. The selling of diathermy apparatus for self treatment at home is a modern form of quackery. It is the duty of the medical profession to denounce the unsupervised home use of diathermy as unsound and dangerous.

MAICO ATOMEER HEARING AID ACCEPTABLE

Manufacturer: The Maico Company, Inc., 21 North Third Street, Minneapolis.

The Maico Atomeer Hearing Aid is a three tube instrument, with transmitter and batteries contained in a single case. The case presents a pleasing appearance, is rectangular with rounded edges and corners and is constructed of smooth ivory colored plastic. The combined "on-off" switch and volume control are located at the top of the case. The tone control or frequency response characteristic of the instrument can be modified by inserting a small screw or screws in the amplifier chassis, which is accessible only after the back of the case has been opened. Either of two different size crystal earpieces for air conduction can be used with the instrument.

Maico Atomeer Hearing Aid.

Dimensions: Case, 4½ by 2⅜ by $\frac{15}{16}$ inches (11.4 by 6.0 by 2.3 cm.).

Weight: Case with batteries, cord and receiver, 7¼ ounces (177 Gm.).

Current consumption: A battery (1.25 volt mercury cell), 55 milliamperes; B battery (30 volt minimax), 0.22 milliampere; battery current is constant regardless of setting of volume or gain control.

Maximum acoustical	Frequency							
gain..........	250	500	1,000	2,000	3,000	4,000	5,000	cycles per second
Large receiver	38.0	43.0	48.0	52.5	49.0	39.0	26.0	decibels
Small receiver	33.0	37.5	42.0	49.0	52.5	48.5	33.0	decibels

These gain measurements were obtained with the frequency response characteristic adjusted for maximum wide frequency response.

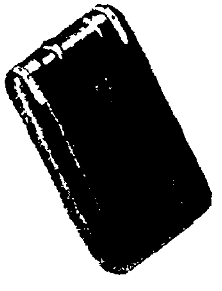
Performance: The Maico Atomeer operates in an entirely satisfactory manner. There is a minimum of inherent, case and cord friction noise.

The Council on Physical Medicine voted to accept the "Atomeer Hearing Aid" for inclusion in its list of accepted devices.

TRIMM VACUUM TUBE HEARING AID ACCEPTABLE

Manufacturer: Trimm Distributors, Inc., 1770 West Berteau Avenue, Chicago.

The Trimm Model #300 Vacuum Tube Hearing Aid is a four tube instrument, with a separate battery pack, consisting of a 1½ volt A battery and a 22½ to 45 volt B battery. The transmitter case presents a pleasing appearance, is rectangular with rounded corners and edges and is constructed of a smooth ivory colored plastic material. The combined "on-off" switch and gain control are located at the top of the case. The frequency response characteristic of the instrument can be varied by inserting one or two set screws in the recess on the side of the case into which battery and earphone plugs also are inserted. Either of two different earphones can be used with the instrument. Receiver #240 has slightly less gain and wider frequency response than receiver #242.



Trimm Vacuum Tube Hearing Aid Model #300.

Dimensions: Case, $4\frac{5}{16}$ by $2\frac{9}{16}$ by ¾ inches (10.9 by 6.6 by 1.8 cm.). The receivers and batteries are of standard or conventional size.

Weight: Case, receiver and cords (but not including batteries), 7½ ounces (212 Gm.).

Current consumption: A battery (1½ volts), 75 milliamperes. B battery (45 volts), 1.0 milliampere. B battery (33 volts), 0.67 milliampere. Battery current drain is independent of volume control setting.

Maximum acoustical gain	250	500	1,000	2,000	3,000	4,000	5,000	cycles per second
No. 242 receiver	39.5	43.5	43.0	52.0	36.5	39.0	26.5	decibels
No. 240 receiver	34.0	40.0	40.5	44.0	51.5	49.5	48.5	decibels

These measurements were obtained with a 45 volt battery, and the tone control was adjusted to give maximum overall frequency response. Insertion of the tone control set screws attenuates the low frequency response. The gain is approximately 5 decibels less with a 33 volt battery than with the 45 volt battery. The gain will be still less with a 22½ volt B battery.

Performance: The Trimm Model #300 Vacuum Tube Hearing Aid operates in an entirely satisfactory manner. Case and cord friction noise are noticeable but not excessive.

The advertising matter appears to be satisfactory.

The Council on Physical Medicine voted to include the Trimm Model #300 Hearing Aid in its list of accepted devices.

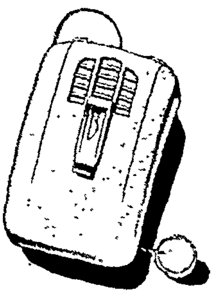
BELTONE HARMONY MONO-PAC HEARING AID ACCEPTABLE

Manufacturer: Beltone Hearing Aid Co., 1450 West 19th Street, Chicago.

The Beltone Harmony Mono-Pac Hearing Aid is a vacuum tube type of instrument of the single case construction. The microphone, amplifier and batteries are contained in a single molded plastic case. The lower half of the case is hinged, giving easy access to the A and B batteries. Volume and tone are controlled by milled disks at the top of the instrument. On and off positions of both controls are clearly marked.

The microphone case is 4½ by 2¾ by ⅝ to 1 inches (11.4 cm. by 7.0 by 1.6 to 2.5 cm.) and weighs 7.7 ounces (218 Gm.).

The magnetic receiver is ⅞ inch (2.2 cm.) in diameter by ½ inch (1.5 cm.) thick and weighs 0.6 ounces (17 Gm.).



Beltone Harmony Mono-Pac Hearing Aid.

Battery Data.—A battery, mercury type, voltage 1.12; current drain, full volume setting, 41 milliamperes. B battery, carbon-zinc type, nominally 30 volts but showing 26 volts under current drain of 0.7 milliampere.

Acoustical Gain.—Measurements of the gain in decibels in the sound pressure level set up in a 2 cc. coupler over the pressure level at the microphone were made at nineteen frequencies between 200 cycles and 4,096 cycles for an input level of 50 decibels measured on the B scale of a General Radio Sound Level Meter. Typical results are tabulated as follows:

Gain (volume control three fourths on):

	Frequency							
Tone Control	256	512	1,024	1,400	2,048	3,100	4,096	cycles per second
"Three dots"	49	52	56	57	49	46	40	decibels
"One dot"	31	41	46	49	44	40	35	decibels

Approximate values of the maximum pressure levels in the coupler were determined at four frequencies with the volume control of the instrument set three fourths on, and tone control on "three dots."

The values obtained were as follows:

Frequency	Input Level	Maximum Output Level
600	70 db.	121 db.
1000	66 db.	120 db.
1400	64 db.	115 db.
3000	64 db.	108 db.

The usual articulation and intelligibility tests were made with a hard of hearing subject with the following results:

Syllable articulation, 94 per cent.
Sentence intelligibility, 100 per cent.

The whispered voice was heard and easily understood at a distance of 5 feet in quiet surroundings.

The instrument is compact and well made throughout and is reasonably free from internal noise.

The Council on Physical Medicine voted to include the "Beltone Harmony Mono-Pac" in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

ESTROGENIC SUBSTANCES (See New and Nonofficial Remedies, 1946, p. 443).

The following dosage form has been accepted:

E. S. Miller Laboratories, Inc., Los Angeles

Solution of Estrogens (in Oil): 1 cc. ampuls and 10 cc. and 30 cc. vials, each being available in potencies containing the equivalent of 5,000 international units per cubic centimeter or 10,000 international units per cubic centimeter; 10 cc. and 30 cc. vials being available in potencies containing the equivalent of 20,000 international units per cubic centimeter of estrone in a neutral vegetable oil, with benzocaine 2 per cent. Preserved with cresol 0.5 per cent.

GLOBIN INSULIN WITH ZINC (See New and Nonofficial Remedies, 1946, p. 450).

The following dosage forms have been accepted:

E. R. Squibb & Sons, New York

Globin Insulin with Zinc: 10 cc. vials. Each cubic centimeter contains 40 units; 0.25 per cent phenol as preservative.

Globin Insulin with Zinc: 10 cc. vials. Each cubic centimeter contains 80 units; 0.25 per cent phenol as preservative.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1946, p. 286).

The following dosage forms have been accepted:

E. S. Miller Laboratories, Inc., Los Angeles

Capsules Ephedrine Sulfate: 25 mg. and 50 mg.

Solution Ephedrine Sulfate: 50 mg. in 1 cc. ampuls. Preserved with chlorobutanol 0.5 per cent.

PENICILLIN (See New and Nonofficial Remedies, 1946, p. 212).

The following additional dosage form has been accepted:

Schenley Laboratories, New York

Penicillin Sodium: 20 cc. vials containing 200,000 units or 500,000 units.

CHINIOFON (See New and Nonofficial Remedies, 1946, p. 262).

The following dosage form has been accepted:

Premo Pharmaceutical Laboratories, Inc., New York

Chiniofon Enerels: 0.25 Gm. tablets coated with shellac.

PHENOBARBITAL (See New and Nonofficial Remedies, 1946, p. 530).

The following dosage form has been accepted:

E. S. Miller Laboratories, Inc., Los Angeles

Tablets Phenobarbital: 15 mg., 30 mg. and 100 mg.

CALCIUM LEVULINATE (See New and Nonofficial Remedies, 1946, p. 480).

The following dosage form has been accepted:

The J. F. Hartz Company, Detroit

Calcium Levulinate 10%: 10 cc. ampuls.

THIOURACIL DERIVATIVES IN HYPERTHYROIDISM

In a previous editorial[1] THE JOURNAL noted the studies of goitrogenic substances by the MacKenzies, by McCollum and by Astwood. These investigations demonstrated that the sulfonamides and thiourea exert a depressing influence primarily on the functional activity of the thyroid and hence on the basal metabolic rate. Thyroid hyperplasia has been shown to be a reflection of increased pituitary activity resulting from the depression of thyroid function. Rawson and his collaborators[2] recorded a lowering of the basal metabolic rate, relief of symptoms, increase of hyperplasia of the thyroid with loss of colloid and increase in vascularity in 19 patients with diffuse toxic goiter treated with thiouracil. They[3] noted also a decreased avidity for iodine by the thyroid gland as shown by the greatly impaired correlation of radioactive (tracer) inorganic iodine with increased elimination in the urine. McGavack and his associates[4] reported the results of treating 26 thyrotoxic patients with thiouracil and reviewed 109 cases reported in the literaure. In 16 of the 135 reported cases there was a toxic or a hypersensitive reaction.

Thiouracil has been used in hyperthyroidism either as a medical treatment per se or as a preoperative treatment in thyroidectomy. In a study of 1,091 cases reported from eleven clinics in the United States and from one clinic in England Moore[5] found that the incidence of untoward reactions from thiouracil was between 8 and 10 per cent. Of these reactions agranulocytic angina, leukopenia and high fever make cessation of drug administration virtually mandatory. A statistical study by Van Winkle and his associates[6] of 5,745 patients treated by 328 clinical investigators revealed that thiouracil is effective against hyperthyroidism both of the diffuse toxic and of the nodular toxic type, but it is not valuable in simple goiter. The optimum dosage schedule appears to be 0.4 Gm. per day in divided doses initially; after the symptoms are controlled or the basal metabolic rate is within normal range the dosage should be reduced to 0.1 or 0.2 Gm. per day. Thiouracil should be used for preoperative treatment or for patients for whom operation is contraindicated. Many patients, particularly those who have received previous iodine therapy, do not respond immediately to thiouracil therapy; hence medication should be continued for at least thirty days or for sixty to one hundred days before concluding that no response to thiouracil is possible.

Granulocytopenia occurs in about 2.5 per cent of the cases treated and is the most serious complication of thiouracil therapy. This reaction tends to occur in the early weeks of treatment; indeed, 80 per cent of the cases were seen by the twelfth week of therapy. Relationship to the dose of thiouracil was not apparent. Treatment of this complication should consist of massive doses of penicillin (500,000 units per day). Leukopenia had an incidence of 4.4. per cent. Drug fever had an incidence of 2.7 per cent seen early in treatment, 85 per cent occurring in the first four weeks but not related to dosage. Skin reactions had an incidence of 3.3 per cent. Urticaria was the most common, but various other dermatoses were seeen. Patients should be instructed to report immediately to their physician if any adverse symptoms such as sore throat, fever, coryza or malaise are experienced.

Rawson points out that one of the disadvantages of thiouracil in the preoperative treatment of thyrotoxic patients is its tendency to increase both the thyroid hyperplasia and vascularity. When iodine is added to the thiouracil preparation, involution of the thyroid and decreased vascularity follow. The time required to prepare a patient for thyroidectomy with thiouracil is longer than that usually required when iodine is used as the sole agent.

A continued investigation of compounds which inhibit the function of the thyroid gland has revealed that appropriate substituents on the thiouracil molecule confer a greatly increased activity. Astwood and VanderLaan[7] have assayed some three hundred compounds for their antithyroid activity and found that 6-ethylthiouracil and 6-n-propylthiouracil are approximately ten times as active as thiouracil in animal tests and five times as active in man as thiouracil. In clinical tests on 37 patients 6-n-propylthiouracil was found to be more active than thiouracil. These compounds were tolerated by patients who had previously reacted unfavorably to the administration of thiouracil or thiobarbital. Untoward reactions were not observed in these cases.

A chance observation by Jeantet of Lyons that workmen employed in the extraction of aminothiazole, which is used in large quantities for the preparation of sulfathiazole, developed goiters without however any signs of thyrotoxicosis and with lowered basal metabolism, suggested that the substance might be useful in the treatment of hyperthyroidism. Perrault and Bovet[8] administered aminothiazole to 129 patients with thyrotoxicosis and did not observe agranulocytosis or any other signs of intolerance reported from the use of thiouracil. They found the drug effective and easy to administer. Wilson[9] in a comparative study of thiouracil and methylthiouracil found that the response to the treatment is more rapid when the latter drug is used and that the maintenance dose of methylthiouracil is smaller than that of thiouracil.

Thiouracil and its derivatives have undoubtedly contributed much to the management of hyperthyroidism. Whether a complete cure by medication alone will be possible is at present conjectural and will probably depend on the development of less toxic derivatives of thiouracil.

VALUE OF GASTRIC LAVAGE IN TREATMENT OF ACUTE POISONING

For a century gastric lavage has been used in treating acute poisoning. Except for some adjuvants, such as use of an appropriate solvent, an adsorbent, such as charcoal, or neutralizing agent, changes have not been made in this procedure. Its value has not been questioned nor its efficiency doubted. However, a systematic examination of the procedure was made in 1942, for the first time, by Harstad, Møller and Simesen of the Pharmacologic Institute of the University of Copenhagen and of the Psychiatric Department of the Bispebjaerg Hospital in Copenhagen[1] with results which indicate its inefficiency and the desirability of more scientific consideration of procedures in acute poisoning.

Møller and his associates made quantitative studies of the volume of fluid and of the amount of poison removed from 80 persons acutely poisoned with several different drugs. Prior to their systematic investigation analytical results over a period of years, obtained from many cases of poisoning without benefit of gastric lavage, had showed extremely variable and sometimes comparatively small removal of poisons. For instance, the hypnotics, especially barbiturates, could be found in rather large quantities several hours after these drugs had been taken. This would suggest the desirability of delayed gastric lavage for promoting recovery. Of the rapidly acting poisons, however, cyanides were found only in small quantities, but nicotine often in large and surely fatal amounts. Yet both drugs are rapidly absorbed. Theoretical explanations might account for these variations, but the first question posed to the Copenhagen investigators was that of the efficiency of the procedure.

The most important features examined were the total volume of wash fluid and the proper use of it. As much as 10 to 40 liters has been recommended, used freely. Møller and his associates proceeded as follows: With the patient in the supine position and a conventional stomach tube in position, lavage was made with lukewarm water through an attached funnel, 1 liter being used at a time up to a total of 10 liters. The volume siphoned off was collected in five portions, the first portion consisting of the amount that could be removed after the first liter, the second after the second liter, the third after the third and fourth liters, the fourth after the fifth, sixth and seventh liters, and the fifth, or last, portion after the eighth, ninth and tenth liters. The five collections of residual wash fluid were then subjected to analysis for the different drugs. Seventy-one of the patients, constituting a majority, were being treated for barbiturate poisoning of variable severity; the majority were unconscious and about 23 per cent died. Treatment was continued with charcoal and magnesium sulfate after the stomach washings had been completed. The striking result was that the total washings from the majority of the patients did not show demonstrable removal of any barbiturate, only small quantities such as 10 mg. being found occasionally. In fatal cases, when barbiturate was not found in the gastric washings the presence of the drug was confirmed in the intestinal contents. There was no correlation between the quantity of poison in the washings and the time interval between lavage and the taking of the drug. Other drugs tested for in stomach washings were acetophenetidin, salicylic acid, quinine, nitrobenzene and tetrachlormethane. However, not more than about 3 per cent of any drug taken was found in washings which gave positive results except quinine, of which 12 per cent was removed. In only 5 of 80 patients who took a barbiturate, aspirin or quinine in tablets or pills was there more than 0.5 Gm. of the poison recovered from the total wash fluid. In these cases the first portion contained the most, or a median of 52 per cent, of the drug (range 3 to 83 per cent), the second portion a median of 11 per cent (range 3 to 16 per cent), the third portion a median of 9 per cent (range 5 to 22 per cent), the fourth a median of 11 per cent (range 2 to 39 per cent) and the fifth the least, or 6 per cent (range 1 to 63 per cent). Although the number of cases was small and the variation considerable, these results show that removal of poisons from the stomach by washing is facilitated by repeated use of smaller volumes of solvent, a time honored principle that is of great practical importance in analytical chemistry.

[1] Harstad, Elisabeth; Møller, Knud O., and Simesen, Margrethe H.: Ueber den Wert der Magenspülung bei der Behandlung von akuten Vergiftungen, Acta med. Scandinav. **112:** 478, 1942.

Consistent with all this were results in dogs with a ligated pylorus and given 2 Gm. of a barbiturate: only 30 per cent of the drug was recovered in the first liter of wash water put into a filled stomach and 22 per cent in the second liter, a total of 52 per cent. From an empty stomach 60 per cent was recovered in the first liter but only 3 to 4 per cent in the second liter, a total of 63 per cent. Other considerations showed that washing with 2 liters in dogs left at least 22 per cent of the barbiturate in the stomach.

An equally important observation made by the Copenhagen investigators was that only 75 per cent of the 10 liters of wash fluid could be removed by lavage. The remainder, or about 2.4 liters, escaped into the intestine. X-ray examination of patients showed that the wash fluid passed rapidly into the intestine. When charcoal was used in unconscious patients, charcoal was found adherent to the bronchi, and microscopically in the pulmonary alveoli, as a result of aspiration of stomach contents. The authors properly conclude that lavage is generally contraindicated in unconscious patients unless there are special indications. However, lavage with use of charcoal is indicated in conscious patients. They recommend that the foot end of the bed be raised, the head turned to its side and an aspirator used to remove vomitus or other material from the mouth.

Here are the general conclusions to be derived from the laborious and highly commendable work by Møller and his associates: Gastric lavage is generally inefficient and often valueless in cases of acute poisoning; its efficiency can be increased by use of relatively small volumes of fluid; gastric lavage promotes passage of a poison into the intestine; when four hours has elapsed after a poison has been taken, lavage is only exceptionally effective; the bulk of a poison leaves the stomach rapidly, especially in suicides, who often take it on an empty stomach; in conscious persons evacuation by emesis with the aid of apomorphine is superior to lavage; lavage is generally contraindicated in unconscious persons but, if done, should be combined with aspiration; adsorption of poisons on the gastric mucosa is important only with heavy metals and a few other substances, removal of these being preferably done by aspiration of contents followed by lavage with 1 to 2 liters of water containing 10 Gm. of charcoal per liter. This time honored method cannot be advantageously applied without recognition of equally time honored principles of physical chemistry and physiology.

AN AMERICAN MEDICAL TEACHING MISSION TO CZECHOSLOVAKIA

In the summer of 1946 an American Medical Teaching Mission[1] spent two months in Czechoslovakia, where for six years (1939-1945) medical teaching and investigation had been completely blacked out by the Nazi occupation. The visit of the American mission initiated a friendly international interchange in medicine that may develop a feature of much importance for the future health and happiness of central Europe. The cordial and indeed affectionate friendship that was exhibited by the Czechoslovakian, Moravian and Slovakian physicians for their American colleagues was heartening.

Czechoslovak medicine, itself at the crossroads, will no doubt abandon the Germanic tradition in education and practice. Whether it will now follow the Western pattern led by the United States or the Russian one or some intermediate one of its own creation (which seems most likely) remains to be seen. Since education in science is largely unitary and since physicians are important in shaping a people's orientation, the way in which Czech medicine does develop can have long range consequences.

For six years all higher education in Czechoslovakia was abolished by the German rulers. Medical students worked at forced labor, melted into the underground or escaped to fight in the Allied armies. Teachers were selected, with other intellectual leaders, for prompt consignment to concentration camps. Perhaps a fourth never reemerged; a few who did were broken men; the remainder are busily rebuilding medical education. University clinics and laboratories and the urban hospitals were little damaged except at the Masaryk University of Brno, where some vagrant bombs missed the railroad station and hit the medical group. Here the departments are being housed in the technical high school, and rebuilding is in progress. Apparatus and equipment were largely stolen or destroyed or, when buried before the Germans arrived, eroded. The libraries were, on the whole, preserved except for a complete gap from 1939 until 1946.

---

[1] The mission, initiated by the Unitarian Service Committee and supported by UNRRA and the Czechoslovak government, included Joseph C. Aub, professor of research medicine, Harvard Medical School; Alexander Brunschwig, professor of surgery, University of Chicago School of Medicine; Leo Davidoff, professor of clinical neurological surgery, Columbia University College of Physicians and Surgeons; Ralph W. Gerard, professor of physiology, University of Chicago School of Medicine; L. Emmett Holt Jr., professor of pediatrics, New York University College of Medicine; Otto Krayer, professor of comparative pharmacology, Harvard Medical School; Josef Lazansky, assistant professor, Tufts Dental School; Milan A. Logan, professor of biological chemistry, University of Cincinnati College of Medicine; Colin MacLeod, professor of bacteriology, New York University College of Medicine; Everett D. Plass, professor of gynecology and obstetrics, State University of Iowa College of Medicine; Emery Rovenstine, professor of anesthesia, New York University College of Medicine; J. E. M. Thomson, president of the American Academy of Orthopedic Surgeons; Joseph Volker, professor of clinical dentistry, Tufts Dental School; Paul D. White, clinical professor of medicine, Harvard Medical School, chairman, and Erwin Kohn, executive director.

The consequences of this period of stagnation and disruption are obvious. Now an unrestrained horde of students has flooded into medicine: 6,000 freshmen medics for a country of 12 million! Three new medical schools were initiated, at Plzen, Olomouc and Hradec Kralove, to supplement the reopened ones at Prague, Brno and Bratislava, but this helps little since the wofully depleted staff and equipment are only stretched thinner. At the great Charles University in Prague, with 3,500 medical entrants, lectures were given in the largest theaters in the city and the preclinical laboratories ran from 8 a. m. to 10 p. m., with each student getting in some score of hours during the year in physiology. The clinics are equally overwhelmed.

Partly in consequence of this situation, medical education is heavily didactic. The curriculum, as contrasted with ours of the present day but resembling our earlier proportions, is heavily weighted toward structural subjects; four years of courses are devoted to histology, gross anatomy and surgical anatomy. There is no opportunity for the student to loiter in some department for special training or research; he must go right through for his M.D. Research in Czechoslovakia, as a result, is anemic in both the preclinical and the clinical area.

The government and the medical leaders are well aware of these lacks and are eager to remedy them. This year's freshman medical class at Prague has been ruthlessly held to 350. The government has appropriated relatively large sums to increase the support of medical science, especially at the preclinical level. Some Czechoslovak medical men are on their way to the United States to learn in our laboratories and clinics, and many more would come at the drop of a visa. Perhaps excellent advantage would derive from a visit by the head professors from one Czech medical school as a group to one of our leading medical schools. On their return, they could introduce, as a unit, a new and forward looking curriculum which would be a pilot plant for central Europe.

Conversely, further movement from here to Czechoslovakia of medical experts, literature and supplies would greatly aid the immediate practice of medicine. American pilot units in physiology, clinical medicine and surgery might be temporarily installed at Charles University in Prague, with benefit to all concerned. The use of anesthesia is backward and, in general, the medical specialties have not been fostered. The eager friendliness with which the mission from the United States was welcomed indicates how much such help is desired.

Current Comment

PREVENTION OF GENETIC DISEASE

Study of the factors and principles of inheritance in relation to disease has developed a relatively new science of great value, the science of medical genetics. In a recent lecture before the New York Academy of Medicine Snyder[1] presented an instructive discussion of the application of medical genetics to public health and clinical medicine. The part dealing with prevention is of special interest. Snyder says that the applications of medical genetics in the field of prevention is of great potential value. "It is becoming more and more feasible," he says, "to prevent in the relatives of persons with genetic conditions the appearance of the abnormality or disease. The procedure is to examine the relatives of an affected patient by means of suitable laboratory tests, in search of the early preclinical . . . signs of the trait. When these are discovered, preventive measures are instituted." He gives two examples: The removal of the spleen of the potential patient with as yet subclinical signs of congenital hemolytic icterus detectable only by appropriate blood tests. And xanthoma tuberosum, a lipoidal storage disease, with possible fatal cardiovascular involvement, which can be detected by blood tests and preventive measures instituted before tumors have formed. These are diseases of dominant heredity and consequently the incidence of affected relatives is high. Probably the method of prevention and cure described by Snyder is applicable also to other diseases of genetic nature than those mentioned. Experience will determine the scope and value of the method.

MORTALITY FROM LEUKEMIA

According to the figures available from the United States death registration area, the crude mortality rate from leukemia has risen from 1.0 per hundred thousand of population in 1900 to 4.3 per hundred thousand in 1944. The rise appears to have been more or less continuous, with a rate of 1.9 per hundred thousand in 1920. Sacks and Seeman,[1] who have been studying the mortality from leukemia, found that white persons are affected at a rate more than twice as great as nonwhite persons, and males at a rate approximately one-third greater than females. According to these investigators, leukemia affects persons in the older ages, particularly after 55, with greatest frequency. More persons in the United States died from the leukemias in 1942 than from smallpox, meningococcic meningitis, scarlet fever, malaria, poliomyelitis, typhoid and diphtheria combined. Since 1940 more than 5,000 persons have died of the leukemias in the United States each year. As the Baltimore investigators point out, there are undoubtedly many deaths from leukemia in which this disease is neither diagnosed nor recorded on the death certificate.

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

DR. JULIAN P. PRICE, Florence, S. C., Presiding

SATURDAY, DECEMBER 7, 1946—MORNING

Function of State Organizations

DR. R. L. SENSENICH, Chairman, Board of Trustees, American Medical Association, South Bend, Ind.: The state societies the executive secretaries and the editors are an important part in the machinery of the organization. It is your task—and you do it very well—of taking information to the profession of your state communities and, in turn, receiving from them the reports of their experience. You assist in the interpretation of experience and interpretation and evaluation of the social attitudes as they are developing. Lastly, you assist in giving form to the thinking and planning of the profession in the state. THE JOURNAL is the medium of communication, and the executive secretary is in contact with the profession of the state and, in large part, assists physicians in improving their local situation. Medical societies have engaged in new enterprises and must of necessity continue to engage in them. You are in business now. In most states you have insurance plans with which you are pretty closely related. We are trying to improve the public relations, and in that also you are important figures.

Dr. Julian Price, Florence, S. C., was elected Chairman.

DR. GEORGE F. LULL, Secretary of the American Medical Association: We welcome you here to headquarters. I can only endorse what the Chairman of the Board of Trustees has already said. We are glad to have you here and to carry on your deliberations at these headquarters. There will also be an opportunity for many of you to carry on informal discussions with members of the staff. I prepared no talk today, but my attention was called to an article in the *Scientific Monthly* for October 1946 from which I will read a few excerpts. The subject is "Running a Professional Society, or the Happy Life of an Executive Secretary." This is written by Dr. Henry Clepper, the executive secretary of the American Foresters in Washington.

(Dr. Lull read excerpts from the article.)

I think that there is a lot in it of good, sound common sense, and it would pay all of us who are employed in executive capacity as secretaries to read the article.

CHAIRMAN PRICE: I want to thank Dr. Lull for the cooperation which he gave to a group appointed at the San Francisco session. At that time five of us were asked to serve as a committee to work with him in getting up the program for today. We met; we made our recommendations, and the program that we have today is the combined effort of this committee of five working with Dr. Lull.

DR. LULL: I want to present to the Secretaries and Editors a new member of our staff here at Headquarters who has a few words to say to you about the Emergency Medical Service Committee questionnaire. Dr. Leland was director of our Bureau of Medical Economics for a number of years and became too ill to continue. The Bureau has had its name changed to the Bureau of Medical Economic Research. We have been fortunate in securing the services of Dr. Dickinson, who was associate professor of economics at the University of Illinois. Dr. Dickinson has been working closely with the Committee on Emergency Medical Service and has just a few words to say about this questionnaire.

Postwar Questionnaire

DR. FRANK G. DICKINSON, Director, Bureau of Medical Economic Research: In the absence of Dr. Bortz, I want to thank you for the splendid cooperation you have given us on this postwar questionnaire. To date we have received the phenomenal return of 30 per cent, and eventually it will probably exceed 50 per cent. About four fifths of the physicians are signing their names to the questionnaire and, as you know, that was optional. About 2 per cent of them are attaching letters, and those letters will be read. It will take us approximately four months to code, punch, tabulate and analyze the results of the questionnaire.

Physicians are not county coroners, yet all of the statistics from Washington and elsewhere have made it appear that physicians served only people resident in the county, and a great many false statements have been made on that account about the absence of medical care. With hard roads and all the other improvements, it seems to us that it is rather silly to talk about the supply of medical service in an area which is a political area, that is a county. The practice of medicine has its economic aspects, and therefore we should develop as soon as possible these medical service areas and then quote the proper number of physicians available for the people in that area, and we shall have a figure on the supply of medical service which belongs in the twentieth century and not in the nineteenth, when we didn't have automobiles and other means of rapid transportation.

DISCUSSION

DR. HOLMAN TAYLOR, Fort Worth, Texas: I should like to ask a question. What would be the real objection to these areas, these trade territory areas, overlapping? It would be absolutely impossible for anybody to determine, for instance, as to the trade territory or area of medical influence as between Dallas and Fort Worth and north Texas and the wide open spaces. With the thickly populated places it is still more impossible to do it. Areas are going to overlap.

DR. DICKINSON: The objection is we don't know how to prorate the physicians for areas that overlap. What is done in most retail trading area studies, of which this is a counterpart of course, is to try by some means to determine whether 55 per cent go to Dallas and 45 per cent go to Fort Worth. If you have any way of determining that as to the number of patients, you can answer the question right there as to where you should draw your line. To which community, to which central community, do the majority of patients in the community go? That is the basis for the answer where you have borderline towns between.

DR. TAYLOR: It is not merely conjecture, but a real problem with all the Southwestern territory. If 45 per cent go to one town and 55 per cent to another nearby, I don't know how you can make the division merely on 5 per cent. What happened to the minority?

DR. DICKINSON: Include the town in question in the area in which the 55 per cent of the patients go rather than in the area to which only 45 per cent go.

State Medical Society Participation in Network Broadcasts

DR. W. W. BAUER, Chicago, Director, Bureau of Health Education: The Bureau of Health Education planned to make the annual series of network broadcasts of special interest this year with the double purpose of marking the Association's Centennial and of identifying the state medical societies more closely with our network broadcasting. A program of medical progress in the past hundred years seemed the most natural choice. In order to tie this program to the state medical societies, the selection of historical events by states or regions seemed preferable. We have but twenty-six weeks of network program. We divided the United States into twenty-five regions ranging from one state to as many as five states.

A brief sketch of the mechanics of handling this program may be of interest, as I have written recently to state society secretaries, urging them to send us more material and to send it more quickly. It was our proposal to have each state medical society, or in regional groupings all the societies concerned, suggest a significant event in medical history in that region as a basis for our broadcast. We proposed to have each program closed by a speaker from within the region, speaking from a station within the region, and briefly summarizing medicine in that area today. The next step was to await replies from the state societies as to their choice of historical events and their nominations of speakers. It soon proved impracticable to expect doctors to travel several hundred miles for a three minute radio talk, so we have been forced to pick the speaker up in his home community if there is a National Broadcasting Company station there. Reversing this procedure, we may have to select our speakers from communities where there are N. B. C. stations.

When the material began to come in from the states, it was apparent that we had assumed more experience with radio on the part of state medical society committees than actually existed. What we were after was personal material about a man, his personality, community relationships, humorous aspects of his career and, in general, feature story material. This we have not received in sufficient quantity to date, with one or two exceptions. May I suggest to you that for a small sum the state society could hire a reporter from a newspaper or a press bureau and tell him what is wanted, and in a few days the reporter will supply a greater quantity of usable copy than would probably be dug up by forty doctors in a year. This is simply because the reporter knows exactly what we want and is accustomed to getting it. After we get the material the script must be written and reviewed. That takes ten days. Then it must be copied and sent to each medical society for review and to each speaker who is to appear in connection with the broadcast. This is good for another five days. It must be mimeographed at N. B. C. because at least thirty copies of a script are needed for production. If we sometimes get a little panicky when responses are long in coming from the states and send urgent telegrams, please do not put it down to inherent meanness. When all this has been done, our next problem is to get the speech from the speaker. This brief summary indicates some of the problems which we face. I hope that when you return to your states, if you have not already done so you will send us your radio material at the very earliest opportunity. We cannot give you your date until we have adequate material for your program in our hands. Until we give you your date, you cannot publicize your broadcast. Without publicity, much of its effectiveness is lost.

The State Medical Society and the State Government

DR. CREIGHTON BARKER, New Haven, Conn.: My experience in government relations has been limited to our own state. I started several years ago to develop the legislative and governmental program of the Connecticut State Medical Society without hindrance from traditional precedent, and I have had the opportunity to see a carefully thought out plan develop. At the state level medical societies can be of the greatest public and political service. It is possible for our societies to develop positions as quasi governmental bodies, and the more nearly they approach this, always maintaining their independence and autonomy, the more useful they will be. If a society accepts these responsibilities unselfishly and with skill it will rate high in public confidence and esteem.

All our states are engaged in activities having to do with the health and welfare of the people, and in one way or another the government does provide some medical care. The planning and direction of these programs lie with citizen boards, and the basis of good relationship with a state government is to have the state medical societies in a position to be consulted about appointments to these boards and agencies. Once this honorable extension of medical society influence has been established, it becomes difficult to put into effect measures which are not compatible with our ideals. Physicians on the boards of such agencies have an unusual opportunity to analyze the effects of proposed measures and oppose them if they are not acceptable to medicine, thus adding the weight of government to the side of medicine and not leave the profession to stand alone as a defensive minority. In contrast we have all seen medical society activities limited to noisy opposition to legislation on the spur of the moment with packed hearings and excited telephoning. I am sure the first, calm, constructive method is the more dependable.

What kind of a person should a wise legislative agent be? No one can answer this precisely. I like the calm, deliberate fellow best. It is not enough to have streaks of shrewdness; wisdom is required. The best two operators in our state are of this type. One of them is rarely seen around the capitol and I have never heard him make a speech; the other sits quietly through hearings and waits until he is asked to express his opinion; this, I may add, is impressive technic. On many occasions we three have discussed the business in which we are engaged. "Don't talk too much," says the one. "Don't waste your time trying to explain things in committee hearings," advises the other friend, "put your information in a memorandum and send it to committee members to read at their leisure." And to this I add "the farmer legislator likes to have you visit him at home during the weekend, when you can talk things over."

I think it essential that the legislative agent for a medical society be a continuous representative of the society, either a full time employee or a member-chairman of the legislative committee who continues in office. He should, over a period of time, become recognized as a reliable spokesman for medicine in the capitol and get on to the ways things are done. I am strongly opposed to the employment of a temporary legislative agent. It is possible for a medical society to retain on a temporary basis brilliant and plausible lobbyists, but I am firmly convinced that medicine loses caste and respect by doing it. Whether layman or physician, a society's representative should always have available expert medical people to advise on technical matters or take part in conferences and hearings. Our method of committee operation is highly satisfactory. We have a number of committees made up of members with special training in various fields of medicine. These committees are officially recognized as advisory committees to government agencies. Three such committees serve the state health department in addition to the two physician members of the Public Health Council. Two committees serve the Department of Welfare, one the Personnel Department and one the Rehabilitation Service, and so on. These committees keep constant liaison between the medical society and government departments operating in the medical field. The Medical Examining Board, which is an official agency appointed by the governor on nomination by the society, has been called on for advice and counsel outside the field of medical licensure and often special committees are asked for to do a special job. Each year we find new ways to assist our government with trained and skilful advisory committees. We have the confidence of government. When the National Selective Service Act went into effect in 1940, our governor and the adjutant general asked the society to organize the medical functions of sixty-five local Selective Service boards and we continued to supervise and operate them throughout the war in the closest cooperation with state Selective Service headquarters. The society also organized and operated two induction centers. Last year, after the passage of the G. I. bill, the governor and the commissioner of education delegated to us the approval under the act of all educational institutions related to medicine, such as hospital residencies, *internships and all on the job training programs* for radiologic, laboratory and physical therapy technicians, hospital administrators and public health personnel. With mutually developed relationships like these, antagonism from our state government is unthinkable.

I would classify the desirable characteristics of a legislative agent in this order of importance: First would be integrity, second patience, next would be a liking for and faith in his job, and last, and as important as all, is a broad knowledge of his state. It is a good thing to know the kind of people you have because people make the political atmosphere of a state. They differ, too, from area to area.

The question arises whether physicians should seek election to state legislative bodies for the purpose of furthering the cause of medicine. While I am hardly qualified to enter the discussion, physicians can surely be valuable in state legislatures, but to be most helpful and a credit to medicine they should go as *citizens first* and take with them knowledge and social understanding and not prejudice.

It is my opinion that organized medicine cannot afford to play party politics. Sooner or later it is bound to be unfortunate if a medical society becomes identified closely with any political party. Our cause is great enough and righteous enough to transcend partisanship. Medicine has two special interests in government. The first is to have unhindered opportunity for the public service that only medicine can give, and the second is to have rights of its own, and I believe that rights will be given in direct proportion to the willingness to accept responsibility.

The Responsibility of the Individual Physician

Dr. James C. Sargent, Milwaukee: I know of no group of men who find it so difficult to compromise differences and unite in a common cause as do doctors. The reason is not obscure. From graduation, the average physician remains, above all else, an individualist. His professional responsibilities call for snap judgment, profound in import and of unrelenting finality. Little wonder that he fits poorly into the hem and haw of a conference table. The one way by which an individual physician might best serve his professional organization is to look critically on those who are to lead him and, whenever he finds them earnest, honest and informed, go along. The power of organized medicine rises or falls with those two salient factors good leadership and a loyal, unquestioning following. I have noted that the men who stay long and move up in positions of responsibility in their professional organizations are men who are blessed with a spirit of service and are willing to do hard work. The executive staff of your society may be active and capable; your councils, boards and committees may be well chosen and work hard on policies and program; but in final analysis effectiveness lies largely in the interest and, at times, the actual leg work of the individual physicians making up your society membership.

It is common sport to belittle the intelligence of the lawmakers of our land and beguile even their motives. Yet I am certain that through your association with them in your official duties you have come to know them as usually fair and sound men trying as best they know how to do what is right for the people they are elected to serve.

If ever there was a time when responsibility rested heavily on the individual physician, it is now. Our national association will continue its efforts at meeting issues head on as they arise in Congress. Your state associations will carry on as before, sending well chosen workers into committee hearings of state legislatures. But how much greater the effect would be if only the individual doctors of our land sensed the power that lies in their hands. There is hardly a legislator-elect in the country today who does not have a personal physician who would be welcome in his home and whose opinions he would hear and appreciate. If our lawmakers of tomorrow were to enter on their new task with that sort of background information, I would hold no doubts over the future of American medicine.

Beset by the great effort that is being made to socialize medicine and, preoccupied by an effort to get some sort of a profession-sponsored sickness insurance plan under way, the profession has hardly had the leisure to give much thought to other problems of moment. Let us see what individual physicians are thinking and doing about them. The Veterans Administration, working arm in arm with the medical schools, is well under way with an expanding program of medical care that bodes well to become the largest health movement that America has yet seen. Probably few, if any, would question the extension of that care to any veteran, or to any of his family, sick or disabled from any cause whatever, if he is in genuine need of help. But to expand and extend its facilities to all veterans, regardless of private means and regardless of whether the disability was connected with military service, is another matter. The limited facilities available and the overwhelming load of service connected disabilities are such that little room remains at this time for admissions other than those genuinely deserving such service. But the pattern is already set. As facilities expand and war casualties decrease, the day will come when we shall have acquired, insidiously and unnoticed, a simon pure system of federal medical practice that will put Wagner, Murray and Dingle to shame. Individual physicians have considerable responsibility in that matter.

In our hurried effort to get to the public a sickness insurance sponsored and controlled by the profession, we are already in fair way to create a frankenstein that can be our undoing. If we have an eye to the lessons of history we must look ahead to the likelihood that whatever we conceive in the way of voluntary sickness insurance will in time become compulsory. If this proves to be the case, as it always has heretofore, our efforts will have been useful only in cutting out a pattern that is workable and right for all concerned.

The general theme of our many profession sponsored plans today revolves around two major premises. First, that it be developed for a low income group unable otherwise to provide for their proper care when sick. Second, that professional fees are to be cut—in general about 50 per cent—in line with our age old custom of "trimming the suit to fit the cloth." I can see nothing but good in such a program, even if it ultimately is to acquire the force of governmental compulsion. But if fee schedules are to place the return for professional services on a cut rate basis, it is imperative that service under our plans be limited to income levels deserving such special consideration. An impossible situation presents itself. Surely the profession does not intend to set up an inferior type of medical service to its insured. And surely it does not propose to create a system that lowers by half the general income level of all physicians. Unless, like hospital insurance, it desires to develop a full pay insurance service for rich and poor alike, it must look carefully and soon to the matter of who are and who are not to be considered eligible for a prepayment service plan designed primarily to meet the needs of families too poor to bear the cost of serious illness without it. The full fees of doctors simply cannot be standardized. There is too great a difference between overhead costs and value of services between your state and mine, between urban and rural populations and between general and special practice. These serious differences do not come into play when the welfare of people in genuine need is involved. They never have. But if our prepayment plans do not draw a clear line between those truly in need and those not, we are building a house of cards that will crumble and engulf us.

I should like to say a few words on the responsibility of the full time executive secretary. I am aware that the clear duty of a paid secretary is to serve the council or board that is delegated to manage the affairs of his society. But his responsibility goes far deeper. He is really subservient to the doctors who pay the dues that finance his organization. And there are times when councilors fail to sense the will of the membership at large or think and act in terms of the special interests of the district whence they come. This is especially true in states in which there are one or more large, well organized county societies. I know the power that you have over the councilors and officers whom you serve. Indeed, I conceive your work to include leadership as well as subservience. And if you were to choose the top man among you I know he would have, among other important attributes, a high degree of native leadership. Organized medicine—thanks to the curious independence of the men of which it is made—needs strong guidance from above, and if you would serve as I think you should, you would never hesitate to use the power of your office in organization affairs that clearly are free from controversy and for the good of the cause. With equal vigor you would avoid a partisan attitude during dispute, whatever your personal convictions are, but in its stead throw your weight into compromise for the sake of unity without which your organization will remain sterile and useless. With that kind of leadership and with a profession slowly but surely learning the strength that lies in unity, the doctors and the public that they serve can look to a future fraught with far less of doubt and trepidation.

DISCUSSION

Dr. R. B. Anderson Jr.,[1] Fort Worth, Texas: Dr. Dickinson made the suggestion that, when these reports come back on medical service rendered by physicians in the county medical society areas, the maps be scrutinized by the state secretary and, if it was thought they were overlapping, they do something about it. If I did not misinterpret the material sent to us from the headquarters office, we were directed to ask the county medical societies to send this material directly to the officers of the American Medical Association. In that event there would be no opportunity for state secretaries to do what Dr. Dickinson asked. In Texas we have been attempting for a long time to assemble some of the material asked for in the questions. In order to make our material complete, we did ask county medical societies to make copies of this material and give it to us. So, in some instances, where they are doing that, we are going to get it.

---

[1] Dr. Anderson died January 2.

Dr. Dickinson: I believe that you were asked that, if the county secretaries found that their lines overlapped, you would ask the county secretaries to get together. I thought that a better way was to ask the state secretaries to see to it that there were no overlapping lines. If there are no overlapping lines it is, of course, desirable that it be sent directly here. But I believe it would be better if the material was sent to the state secretary first. Had I known that at the time, I would have suggested it, but I did mention in the communication which was attached to the map that if there were overlapping lines, please ask the secretaries concerned if they would get together and see if they could eliminate that. The method of procedure suggested is as follows: Select a typical week. During that week have the office girls in the physicians' offices in Dallas and Fort Worth compile the number of patients from these doubtful border towns in the overlapping area. Assign these border towns to the Fort Worth medical service area from which more patients during the test week came to the offices of the Fort Worth physicians. Other towns in this overlapping area would be assigned to the Dallas area, if more patients went to Dallas during the test week. That would be a statistical method, simple and, perhaps, definitive by which you could determine where these border towns belonged.

Dr. Taylor: Fort Worth and Dallas aren't the only two medical centers in Texas. We have county societies comprising as many as ten counties and perhaps within the boundary of that area as many as two or three real but small medical centers. That complicates our problem no little.

Dr. Dickinson: I also added that I am asking the University of Illinois Bureau of Business Research to send you a copy of the publication in which they marked off the state of Illinois in retail trading areas. There is no overlapping at any place in it. Although I appreciate that the problem of medical service areas is a different matter in many respects, it might suggest the ways and means by which it could be done. The hardest job is to select the centers of the medical service areas.

Dr. Anderson: Back in the days of the Procurement and Assignment Service, we had very much the problem that you are talking about. In other words, we used our county medical societies as areas to determine how many people they served. We put on the advisory committee in each county medical society the responsibility for determining just how many people the doctors in the county medical society areas served. We believe county medical society committees can do this job better than anybody else. We tried to impress them with that responsibility. Carrying this thing forward into the present status, we have what we call county medical service committees, and they are asked to furnish these data which you have requested. They will be the ones who will set up the population served by the physicians in the county medical society area. We don't doubt but the circle is going to overlap all over Texas because there isn't any other way you can do it. But, when you take the whole picture, you will have something fairly definite to go by.

Chairman Price: We have time for decision on the suggestion made this morning, and that is that we make plans for a committee of our own membership to help make up the program for next year. It has been moved and seconded that such a committee be appointed. Carried.

Dr. Creighton Barker, New Haven, Conn.: I would move that the Chair appoint a nominating committee of three to select such a committee.

Chairman Price: Moved and seconded that the Chair appoint a nominating committee who will, in turn, nominate a committee of three or five, whichever they think best, to work with Dr. Lull in preparing our program for next year. I will appoint Dr. Weld, Mr. Dick Graham and Dr. William Brooksher.

Saturday, December 7, Afternoon

Chairman Price: I am going to ask all of those attending this conference for the first time as editors, secretaries or executive secretaries please to come forward. So, I am going to ask these gentlemen, in turn, to please stand up and face the audience and give your name and your newly acquired position, so we will know who you are and where you are from.

State Medical Associations and Social Security and Federal Income Taxes

Mr. Thomas V. McDavitt, Chicago, read his paper.

DISCUSSION

Dr. Barker: I should like to ask what we are doing about advising our county associations of this tax affair.

Mr. McDavitt: Dr. Barker, I don't regard a ruling, for instance, with respect to the Connecticut State Medical Society as having any particular bearing on the question of a county society's liability. The test is to determine in the light of each society's activities.

Dr. Barker: That is what was in my mind. What I want to do is to direct a question to others here as to what sort of aid and guidance they have given with respect to the finances and the tax status of county associations within their state organizations.

Mr. Richard H. Graham, Oklahoma City: To answer Dr. Barker's question for me in a little more elementary fashion, you say that each county medical society should have established its own status?

Mr. McDavitt: I think particularly if they have any employees connected with the county medical society. I think some of the larger county medical societies, like Wichita or Sedgwick County, Kan., certainly should have a separate status; certainly if you have a large office for Oklahoma County; certainly the five boroughs in New York, several academies in Ohio or Wayne County in Detroit.

Mr. Graham: Do you know if those have been established and what they were?

Mr. McDavitt: Frankly, I would like to have had time to send the questionnaire out to the larger county societies but I didn't have time. I know that Wayne County, Mich., has established some sort of a status.

Dr. Holman Taylor: Isn't it true that the state medical association has no members except those of county medical societies? Isn't it true that the county medical society is the state medical association? Then, how could they be any different and subject to additional taxation in the state association? Years ago our state association sought to establish the right for county medical societies to secure articles of incorporation in spite of the fact that the state medical association was also a corporation. We had considerable difficulty in securing incorporation of county medical societies because of the fact that they were a part of the state medical association. Then, how could they also be made to pay taxes? We got by with it. Most of our county societies are incorporated.

Mr. McDavitt: From the standpoint of medical organization, with one or two exceptions, the state medical societies are separate, incorporated bodies; that is, one group of state medical societies. They are composed, in turn, automatically, of members of their component county units, which, from the standpoint of income taxation, are separate organizations.

Dr. Taylor: They are not separate organizations—county societies.

Mr. McDavitt: Yes, I think they are. You have to take ipso facto, by virtue of the membership in the component societies, the members of the component societies, but the state society is an entirely different, distinct and separate organization from the county societies.

Dr. Taylor: There isn't any state medical association, if your logic is correct, because they are only members of the state medical association.

Mr. McDavitt: Then we haven't any separate American Medical Association by that.

Dr. Taylor: Yes, you have.

DR. BARKER: Isn't the question that comes in here the fact that the county associations have independent income of their own? It does not accrue to the benefit of the state society. That really is the point here, as to whether or not they are liable for income tax.

MR. McDAVITT: It is a separate organization, with separate income.

MR. OLIVER E. EBEL, Kansas: The Internal Revenue Department swooped down on all of our county societies and declared them all taxable overnight. Three or four of them paid income taxes and penalties and back taxes totaling four, five or six thousand dollars in penalties. The reason was that these county societies had made contracts with the boards of social welfare for treating indigent people. Then they became a contracting party, and they paid the individual doctors. Therefore the members of the county society were held to be employees of the county medical society. Therefore the total income of that society inured to the benefit of the individuals, and they were all held taxable.

MR. McDAVITT: Under the income tax act?

MR. EBEL: Yes, on income tax, because both 101 (6) and 101 (7) say that no part of the net earnings must inure to the benefit of members. It had in both of those instances. So these county societies have all caught the fulcrum on the program and have had to rearrange the contracts whereby each individual physician was a separate party to the contract under the social welfare program. That is what they did to us. That left the state society entirely apart. We are still exempt. We had nothing to do with that. They are rearranging the program, but they had to pay penalties and taxes.

MR. W. G. FREY JR., New York: The Medical Society of the County of Queens, Incorporated, one of the five county medical societies in Greater New York, was assessed by the Federal Income Tax Bureau for income tax delinquency on the grounds that we were engaged in lobbying because we had a legislative committee which attempted to influence the legislature in favor of the medical society. An appeal was taken, which was overruled in the first instance, and a second appeal was taken. Finally, on some technicality the medical society was not assessed for income tax. Since then the society has been very careful in its budget not to allot any money to the legislature committee. They get around it, but they are not engaged in lobbying.

MR. GRAHAM: On the basis of this reasoning in Kansas, is there likely to be any ramification of taxation with these agreements that we are making with the Veterans Administration?

MR. McDAVITT: I haven't thought that out. I was trying to confine myself today to state medical societies.

MR. GRAHAM: The courts have peculiar ways of rendering decisions. I can see the possibility of an agreement with the Veterans Administration for payment of fees to members that they may be considering.

MR. McDAVITT: As a matter of practical law here, all the income tax that is going to be levied on you is going to be a certain percentage based on net income. In the Veterans Administration program you are taking 7 per cent for administrative expenses. If you spend all of the 7 per cent for administrative expenses there is no net income is there?

MR. GRAHAM: Certainly, the members are benefiting from the contract.

MR. EBEL: We checked with our attorney on that question. It happens to be an agreement between the medical society and the Veterans Administration, but it is the administration that pays the doctor directly, and the medical society doesn't have the money. So you are exempt under that basis.

DR. P. E. BLACKERBY, Louisville, Ky.: The doctor individually pays that income tax.

DR. W. P. ANDERTON, New York: To avoid that possibility, we formed the Veterans Medical Service Plan of New York, Incorporated. That avoids the trouble of the society taking money from the Veterans Administration.

DR. BARKER: We went very carefully into this in our agreement with the Veterans Administration. We were advised by counsel that it expressly states in our agreement with the Veterans Administration that we are to receive nothing. Furthermore, none of the money paid to physicians by the Veterans Administration under this agreement passes through our hands. It is paid directly to the individual. It is expressly stated in our agreement that we are not to expect or receive recompense.

MR. H. VAN Y. CALDWELL, Cleveland: I can give our experience. Our attorneys advised us not to operate cancer detection clinics or take the money for them, so we set up as a community committee, to operate them.

CHAIRMAN PRICE: As many of the secretaries or executive secretaries as would like a mimeographed copy of this paper, please leave your name and address with Mr. McDavitt. This morning we had a discussion of the state medical society and of the individual physician. Now we will hear a discussion of the county medical society.

The County Medical Society

MR. M. L. MEADORS, Florence, S. C.: In a recent publication of the New York Trust Company it was stated that during the year 1944 more than four billion dollars was expended in connection with medical care in the United States. Medicine it was said has become big business. In this growth in the practice of medicine, to the point where four billion dollars is invested therein by the people of the United States in one year, there possibly has been a tendency to overlook the most important element in the structure of the entire organization—the county medical society. These units, collectively, form the broad base which supports the entire edifice. Yet the county medical society, in some parts of the country at least, has been relegated within recent years to the position of a small social group or scientific essay society. Except in the larger centers of population the medical meetings are attended by a mere handful, the program is devoted to the discussion of papers on some phase of medical practice, and the value of this group from the standpoint of the economics of the profession has been largely overlooked.

The importance of the county society in this respect results from two factors: First, it furnishes the most direct, immediate personal contact not only among the doctors themselves but between the doctors and their friends among the laymen. Through this organization, more than through any other, it is possible for the physicians to reach those outside the profession whom they wish to contact. In brief, the county society is closest to the people. Therefore, and this is the second factor, it is closest to the lawmakers, whether they are members of the city council, the board of county commissioners, the state legislature, or Congress. Every member of Congress lives within the geographic area of some medical society. Within that area, which constitutes his legal residence and wherein his home and closest associates are located, is the place where your Congressman's principal interests lie and where his ear is most acutely attuned to the wishes of the people. In nearly every case some of the doctors themselves are numbered among the lawmakers' closest friends and associates. The county society is by far the most effective medium for reaching the lawmakers. All of the lobbying that can be done by the legislative committee of the state organization, all of the publicity and other means which may be employed, are far less effective than personal contact with the members of the legislature by his constituents in his home community. These are the people who maintain him in office. A personal interview with the representative, preferably in his home town during a recess of the legislative session, will do more toward winning his support of legislation in which the physicians are interested than almost any other means.

With the growing realization of the value of good public relations, the importance of the county medical society as a medium for launching and advancing such a program should not be overlooked. One of the most difficult obstacles in the way of successful public relations is the indifference by the doctors themselves toward the economic phase of their work. It is primarily a problem of education with them, as well as with the public. Undoubtedly the public needs to be educated, but before substantial headway can be made toward education of the public there must be education of the doctors—education as to the need and manner of cultivating public relations. Comparatively little has been done by the profession along the line of directing or shaping the form of legislation. The profession has not been given the opportunity to take an active part, but in large measure the reason why the opportunity has not been extended is that the legislators realize in advance the critical and indifferent attitude of the profession, the feeling by physicians that in attempting to regulate such things the laymen are trespassing on hallowed ground, sacred to the profession itself, and that no cooperation therefore could be expected from the latter. There should be further and rapid development of professional thought along the line that laymen do have a stake in the business of medical care, and in this sense the physicians themselves need further education.

In achieving a somewhat different attitude of the profession to the public, the county society is the very point of beginning. That is the first purpose it may serve. But it can assist actively in the solution of all the problems before us, first, by devoting ample time regularly at its meetings to consideration of the economic phase of medical practice and, second, by participating actively in projects of any local or state agencies which are concerned in any way with preserving or improving the general health and medical care of the people. The time allotted for the purpose at the meeting might be devoted to consideration of a number of subjects. First in importance would be the health needs of the community from which the membership of the society is drawn. Often the tendency is to overlook the needs around our doorstep while attempting to correct the wrongs beyond our reach. An active, energetic interest in conditions which require improvement would go a long way toward impressing local citizens with the profession's sincere interest in the people with whose medical security it is charged. Let the medical society become as actively interested in the community's health as the chamber of commerce is in the community's business. It might be feasible for a county society to attempt to collect and maintain records on the incidence of disease and study together the types most prevalent in the community, to conduct some sort of investigation of its own into possible sources of infection and to advise the municipal or county authorities of any change which a majority of the members of the society believe to be in order.

It has seemed to me that there should be a more direct connection between the county medical society and the department of public health. There is little in common in most communities. Perhaps that is not in most cases the fault of the medical society. The services of a lawyer are at the disposal of the courts for the indigent accused. All the scientific information and knowledge of the doctors in the community should be available to the public health service or to the county and city departments of health, and the latter should be encouraged to make use of them. It is unfortunate for the profession and for the public health service if the people obtain the impression that any degree of antagonism exists between the two groups. The county society can help to dispel it.

There are projects in every state, in every community, concerned in one way or another with the health of the people, and the society can profit greatly if it will give material assistance by identifying itself and becoming actively connected with such projects as are worthy. The public is interested in the welfare of the medical profession and sympathetic with it only to the extent, and so long as the public is convinced, that the profession is interested in the welfare and health of the public. With the increase of specialization, much of the personal touch between the physician and patient has been lost. The practice has come to appear, to many people, more of a business than a profession. The right of the physician to specialize and to limit the hours when he will be available to patients cannot be denied, but he must be resigned to the loss of the enjoyment of a certain measure of the former attitude of implicit faith and sympathy from his patients in exchange for the increased convenience and income derived from the new mode of operation. The effect of the change can be somewhat offset by a real genuine interest in matters which pertain to the health of the people, aside from the service for which they are paying, and by the demonstration of that interest by taking part individually and through your organization in the activities which are designed to increase and improve the standards and availability of medical care.

An illustration of what can be done was a recent experience in South Carolina. The medical college of that state has a long history and splendid background. But it is small and its facilities are very limited. Two years ago a plan was formulated for its expansion requiring a large investment. Despite strenuous effort on the part of the board of trustees and others, the measure which would have provided the appropriation was defeated in the legislature. Then the matter was presented to the South Carolina Medical Association. A committee of seventeen doctors representing all parts of the state was appointed to study the plan. Meetings were held, the college was visited by the committee and its plant and facilities were examined in detail. Then on the recommendation of the committee the plan was adopted and endorsed wholeheartedly by the house of delegates and the committee was enlarged to forty-six to include one doctor from each county medical society. The members of this committee began their activities in their counties weeks before the meeting of the legislature and continued while the bill was under consideration by the lawmakers. Arrangements were made to have the president elect of the state medical association and chairman of the committee address the joint session of the senate and house of representatives immediately before the time fixed for the decisive vote on the bill. The result was that at the 1946 session the bill was passed by an overwhelming majority and carrying an even greater appropriation than had been suggested. It is generally conceded in South Carolina that this was the direct result of the activities of the state medical association acting through the committee composed of members from each county society.

All the activities which might be undertaken should be brought clearly to the attention of the public, particularly those things which have to do with the health and the availability of medical care to the people generally. The accepted mediums are the press and the radio. Other opportunities will be presented from time to time. They are all about us if we will only notice and seize them, opportunities to address various organizations and groups, service clubs, welfare organizations and business and professional groups. The county society is the only logical unit through which many of these things can be arranged, and an alert organization can find the opportunity as often as would be desirable.

Do not make the mistake of thinking that, because you do not hear criticism, it does not exist. One of the advantages in having some one outside the profession associated in this capacity is the fact that people will express their views and criticisms more freely to him than they would to doctors. Prepare to meet criticism, the arguments in favor of regimentation and of reforms contrary to the best interest of the profession by discussing them publicly. You will convince the public of the sincerity and good intentions of the profession, and you will provoke the expression of feelings and arguments from the other side which will enable you more effectively to meet the issue.

Information such as I have referred to, as to the activities, the interest of the profession and medical care for and the health of the public generally is far more effective than vindictive articles and speeches criticizing legislators and all those connected with politics or pressure groups or, on the other hand, devoted to extolling the unlimited virtues of members of the profession and lamenting the passage of the good old days. The national organization has realized fully the necessity of a constructive attitude. The point at which the most effective constructive attitude and action should originate is the county organization and through its members as individuals.

The Cooperative Medical Advertising Bureau

DR. STANLEY B. WELD, Hartford, Conn.: This is the first year that the chairman of the Advisory Committee of the Cooperative Medical Advertising Bureau has rendered a report to the Conference of State Secretaries and Editors. This report is being made in order that each state journal may be fully cognizant of the changes that have transpired in the Bureau during the past four years and may be better informed of the progress of the Bureau.

The Cooperative Medical Advertising Bureau was organized in December 1913 by the Board of Trustees of the American Medical Association on mandate from the House of Delegates. The main purpose of the Bureau was to aid the Council on Pharmacy and Chemistry to effect some sort of rationale in therapeutics by securing advertising conforming to the rules of this Council. Originally twenty two state medical journals were represented by the Bureau, although all had been invited to participate. The membership in the Bureau has now increased to thirty-five journals, which are the official publications of forty-two state medical associations and includes all state owned publications except those of Illinois and New York.

In 1943 dissatisfaction was expressed by several of the member journals in the lack of expression permitted the state journals in the operation of the Bureau and in the limitations placed on the advertising copy by the rules of the Council on Pharmacy and Chemistry. For a year the editor members of the Advisory Committee listened to complaints and commendations from the state journal editors and held meetings of the committee in order to effect certain changes in the management of the Bureau. A new set of operative principles was drawn up calling for a further increase in the size of the committee to eight members. The five elective members were to be editors or business managers of state medical journals, each elective member to be a member of the American Medical Association. An important item in the new operative principles is the appointment by the Board of Trustees of a liaison committee of the Council on Pharmacy and Chemistry to meet with the advisory committee of the Bureau. On March 9, 1945 the committee met with the Council on Pharmacy and Chemistry in an effort to bring to the attention of the Council the desirability of revising the Council's official rules, which had been in operation for forty-one years. This the Council did, and the new rules were published in The Journal early in 1946. These revised rules contain two radical changes, one relating to the subject of "protected" names. The Council has decided to withdraw this rule and to admit multiple names, with the provision that the manufacturer give equal prominence to the common "unprotected" name that is or will be provided. The other change is in the broadening of the Council's attitude toward "advertising to the public," permitting such advertising when it is judged that its dangers are less than its benefits.

In December 1945 the Board of Trustees advised the committee that the administration of the Bureau would be a function of the Board of Trustees on consultation with the elective members of the advisory committee; that member state journals would abide by the accepted principles governing operation of the Bureau.

The real important work of the Bureau is to sell space to national as well as to local accounts, to service the accounts, to distribute copy and plates, to review copy for its acceptability, to handle the financial details of billing, to collect accounts and transmit remittances each month to the journals and to refund surplus monies in December of each year. Virtually all the revenue involved eventually reaches the offices of the journals, minus the appropriation necessary for conducting the Bureau, which amounts to less than 5 per cent of the net sales at the present time. The 25 per cent commission from monthly payments of the Bureau to the journals is for the purpose of establishing a working fund during the Bureau's fiscal year, and it is refunded at the end of each year. No deductions are made by the American Medical Association excepting $2,400 a year for accounting costs. The expenses for Bureau salaries, printing and other necessities are, of course, deducted from the appropriation fund and the Association offers its full facilities in the operation of the Bureau. This is real economy in selling advertising space and, at the same time, it enables the journals to carry national advertising of ethical accounts that otherwise would be difficult to secure without involving a great deal of expense, since the average cost of selling is from 20 to 25 per cent. Basing this on the present net revenue, which hovers round the $600,000 mark, the cost would average from $120,000 to $150,000, whereas the Bureau budget runs slightly over $20,000 a year. Furthermore, the Bureau is in a position to render many additional services, in supplying information of every description obtainable at A. M. A. headquarters. It is essential that the journal offices extend their closest cooperation by answering promptly all inquiries received from the Bureau. It would be well to assign some one in your office to answer these inquiries. The Bureau is endeavoring to secure copy instructions and plates early each month to meet your printing schedules and to send your checks not later than the 15th of the following month.

Standardization is important. Standard colors have been established to enable your printers to handle their work on schedule and to permit the printing of several colors in the same form, thereby reducing printing costs. We should also endeavor to have uniform charges for preferred positions. Another important matter is to permit the Bureau to clear national accounts whenever possible. Some accounts are now divided, part through the Bureau and part on a direct basis. This makes it necessary for the agencies or advertisers to deal with several journal offices in addition to the Bureau, requiring separate billing, renewal of contracts and so on. The Bureau is a part of *your* organization for selling and servicing advertising accounts, and there should be no competitive thought so far as direct sales and Bureau sales are concerned. Frequently agencies send space orders directly to the journals by mistake and they are retained by the journals; then, when copy instructions come through the Bureau, it becomes confusing to all concerned. May I emphasize again that the closest cooperation should be maintained.

In closing, may I remind you that only as you maintain a high editorial standard for your journal and endeavor to improve the format, the content and the technical printed product will you appeal to the reader and to the advertiser. If we can offer to our advertisers an excellent journal in every state the success of the Cooperative Medical Advertising Bureau will be enhanced. We have been enjoying an all time high in state journal advertising. It cannot be expected to continue without an effort on our part to supply in return a product worth every nickel our advertisers invest in us.

Mr. A. J. Jackson, Director, Cooperative Medical Advertising Bureau: I have prepared a chart which shows the progress made in revenue, beginning in 1918 to the end of this year, an increase of about 1,500 per cent from its inception. Practically all of that money is distributed to the state journals.

The Medical Profession and Public Relations

Mr. Charles M. Swart, Chicago: It is seldom that a public relations man has the opportunity accorded me by the American Medical Association in my first two weeks in headquarters —the opportunity of meeting and talking with the people who are close to the points of contact at which public relations are made. Public relations are the sum total of private relations. The relations which the individual physician has with his patients, with other professions, organizations and occupations, and with his community are the basic elements of public relations of the medical profession. The relations which the county medical society has with its community set the tone which will largely characterize the relations of the profession and the state and national associations in that community. The relations which the state association has with all the elements of public opinion in its commonwealth is more potent than anything a national organization can do to affect public opinion in that state. Recognizing this, your national association is planning a large part of its public relations program around the cooperation of the state and county organizations. One of the first things that we hope to do is to establish a direct line of communication between the national headquarters and the officials of the state and county organizations. This will be in the form of a periodic news letter from the general secretary to key officers and physicians throughout the country —designed to keep you abreast of work in progress at 535 North Dearborn Street—work which is being done in the interest of the profession and the health and welfare of the public.

By the same token I want to ask each one of you to take the personal responsibility of keeping our office informed as to what is going on in your state and county organizations: anything that bears on public relations, any programs that you are initiating or operating which promise to bring results, any problems which you have which we might help you to think out or solve.

Just as the American Medical Association cannot work alone to improve the public relations of the medical profession in the nation as a whole, so the state and county societies cannot work alone in their respective communities and expect to reach their goals successfully.

The medical profession sometimes finds the public hostile, unsympathetic or indifferent to its problems. Because the men who make up the medical profession are of good will, intelligent and dedicated to service of humanity, it is frustrating to find other community leaders hostile, unsympathetic or indifferent, especially when we know that these people do not understand the basic elements of the problem and its proposed solution. But we can have the wit to win. We can take them into the ranks of our supporters and allies by creating opportunities to call on them for consultation and cooperation. Each county and state association can study the health problems and hazards of its own community.. Each can select a specific issue. Each can form a temporary committee of doctors interested in the various aspects of that problem—a committee which will control the medical aspects of any program to solve the problem. Then, the community leaders can be called in, the men and women who lead, direct and mold public opinion. We can work with these people and through this contact get them to know and understand our problems, our methods and our goals. There is nothing as potent as participation to win respect and support.

The medical profession is sincere in its efforts to safeguard the health of the nation. Individually and collectively, medical men have been demonstrating their sincerity through advances in medical education, science, drugs and treatment procedures, and through individual devotion to duty. Unfortunately for the medical profession but disastrously for the public welfare, there are numerous people willing to follow those who would discredit the sincerity of the medical profession. The only way to combat such false leadership is to provide good leadership—to give the community leaders an opportunity to participate under medical leadership in convincing demonstrations of our sincerity of purpose. That is public relations in action. I want to comment on the instruments of publicity and public relations—newspapers, the radio, pamphlets, posters, exhibits, movies and speakers. A news release on the front page of the paper contributes nothing to your public relations. until it is read and creates an attitude. A radio program is a total loss to public relations until thousands of listeners tune it in and hear and believe in its message.

Your national association has plans, which are rapidly becoming active, to provide the heavy artillery of publicity and public relations in all of the national mediums and to supplement your efforts in the local areas. It is our job in the national office to prepare the way and to give all the support to the effort that our resources can afford—but the medical profession cannot take and hold the ground of improved public relations without the complete devotion and cooperation of the state and county societies which are out on the firing line where public opinion is made.

My association with the medical profession has been lifelong. I am looking forward to the day when I come out to meet you on your home grounds, to know you personally and your public relations problems intimately. Until then, let's keep in touch with one another.

CHAIRMAN PRICE: I am going to call on the chairman of our nominating committee to nominate the committee which will work with Dr. Lull in presenting our program next year.

DR. STANLEY B. WELD, Hartford, Conn.: For chairman, Mr. Theodore Wiprud of the District of Columbia Society; and on the committee with him, Mr. Harvey T. Sethman of Colorado State Medical Society, Dr. Douglas L. Cannon of the Alabama Association, Dr. Dwight Wilbur of the California society and Dr. Jonathan Forman of the Ohio State Medical Association.

SATURDAY, DECEMBER 7, DINNER SESSION

DR. E. G. JOHNSON, President, Nebraska Medical Society: Dr. Arthur L. Miller of Kimball, Neb., is the representative from my district, the Fourth Congressional District. He has had long experience in medicine and later served as Director of Public Health of the state of Nebraska and president of the Nebraska State Medical Association.

What's Ahead for the 80th Congress?

HON. A. L. MILLER, Kimball, Neb.: The new Congress will have the job of deflating the overstuffed Frankenstein, bureaucratic monstrosity of government which for the past twelve years has been trying to regulate everything from your shoe strings to your hair tonic.

One needs but review the results of the November election to realize that the Communists, the left wingers and those advocating more government controls received a severe set back.

There were 30 members in the last Congress who consistently voted for more government controls and regimentation of the American people. They were defeated.

There will be 102 new faces in the House of Representatives in this Congress. In reviewing the political campaign literature of this group, one is convinced that at least 90 per cent of the new members believe that the people are tired and fed up with regulations and controls. They have had enough of being pushed around by their government. The people want less government in business. They want less bureaucracy, regimentation, communism and controls. It means that the socialization of America and the radical Political Action Committee's legislative program suggested to the 79th Congress, if proposed, will be thrown into the ash can. The election was not so much a Republican success as it was an American victory.

See how bureaucracy has grown. In 1933 it required but 533,000 federal employees to run the government, at a cost of a billion dollars. Our national debt at that time was 16 billion dollars. In 1939 there were 933,000 federal employees, which cost 3 billion dollars in salaries. Our federal debt at that time was 60 billion dollars. Today there is something over 2,300,000 on the federal payroll, which cost 8 billion dollars to maintain. The federal debt is 260 billion dollars.

Senator Byrd of Virginia, in a recent report, said there were 1,141 various government agencies and commissions. There are 32 dealing with housing, 37 with foreign trade, 93 lending the people's money, 26 dealing with health, and 15 have their finger in the sugar pie. He states that these agencies have issued 107,980 regulations, which have the full force and effect of law without the approval of Congress.

The Congress will take definite steps to throw the Communists off the payroll of government. One needs but to read the statements of Attorney General Clark and J. Edgar Hoover to realize that the virus of communism has been slowly soaking into our circulation. Communists have connived and worked their way into policy forming jobs in government. There is no question but that it is a blue hued cancerous growth which must be eradicated from our body politics.

Legislation affecting labor, industry and the public will have high priority in the next Congress. In my opinion legislation will be adopted which will make labor and industry responsible for their contracts; legislation which will outlaw secondary boycotts, sympathy strikes and jurisdictional disputes. Present labor laws will come in for some revision. The legislation adopted will be in the interest of the public and not weighted on the side of labor or industry.

The 80th Congress will be an American Congress. It will have great powers and responsibilities. It will take steps to restore constitutional government, which, in the past, has permitted the individual with ingenuity, imagination and initiative to penetrate the new horizons of the future. The Congress will give new force and direction to those inventions, discoveries and technics which hold the key and are an integral part of our nation's growth. Man's ingenuity, under free enterprise in the past, has had no limits. We cannot have a free and hopeful people if they are dragged down by debt and the tax collector. We cannot have freedom in the slavery of a host of government restrictions. We cannot continue to smother the opportunities of small people by a big government, big strikes, big political monopolies, big scarcities and big blunders.

Now as to medical legislation: We shall probably have another Murray-Wagner-Dingell bill. It will be greatly modified. It may resemble some provisions of the Taft-Smith bill. We shall undoubtedly deal with bills relating to cancer and the continuation of some emergency maternal health program. I do feel, however, that no radical socialized medicine bill will have any chance in the present Congress.

May I suggest that the Secretaries have a job of selling good medicine to the country. It does seem to me that we must keep up a good public relations program through the paper, radio and forum discussions. I am convinced that the Secretaries and medical men must lead the parade in helping to mold and shape public opinion.

(To be continued)

Washington Letter

(From a Special Correspondent)

Feb. 20, 1947.

Administration Revives Demands for Nationwide Health Insurance

Introduction of the Taft medical care bill in the Senate was followed by revived administration demands for a nationwide health insurance program. In its eleventh report to Congress, the Social Security Board called for a health insurance program backed by contributions from workers and employers, similar to those for old age benefits. The board attacked the "free treatment" principle, declaring that most normally self supporting persons prefer to have a system of prepaid medical care rather than to have to seek free care when reduced to dependency. President Truman in his state of the union message rejected charity methods and called for a national health program as one of the most important items in his whole social welfare plan. The board denied that its program, which contains numerous other welfare provisions, is "socialized medicine," but claims rather that it is a method of "insurance payment."

Shortages of Doctors, Nurses and Hospitals

In his annual report for 1946, Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, declared that "there are not nearly enough physicians, dentists, nurses and other health personnel to go around, nor enough hospital beds and clinics to take care of our minimum needs." Many areas have no doctors or health facilities. He declared that the last frontiers of public health were to conquer the diseases of advancing years and to extend health services to the entire population. He said: "We have yet to solve the economic problems of medical care. We have yet to make it possible for every one, regardless of income, to obtain the basic services needed for the protection of his own health and that of his neighbors. These are our basic objectives for the future."

Public Health Service Seeks Fifty Million Dollars to Start Hospital Construction

Congress will be asked by the U. S. Public Health Service for 50 million dollars to start construction of hospitals under the five-year, $1,125 million federal-state hospital building program authorized by the last Congress. Surgeon General Thomas Parran has issued regulations under which states, local governments or nonprofit institutions may collect $1 in federal funds for every $2 of local money spent on new construction. The seventy-ninth Congress appropriated $2,350,000 to assist states in surveying their needs and authorized annual appropriations of 75 million dollars for construction.

Uncle Sam Profits from Sex Hormone Factory

Donald C. Cook, director of the Office of Alien Property, revealed to the Senate Civil Service Committee that Uncle Sam is making money as owner of a male-and female sex hormone factory, the Schering Corporation, headed by Frank C. Brown. Mr. Cook said the property gives the United States government a 10 million dollar annual income as against a 4 million dollar administrative cost. The plant is alien property seized during the war.

Mine Operators Term Lewis Health and Welfare Fund "Economic Blackmail"

Spokesmen for United States coal mine operators told Congress that they would not pay the John L. Lewis tonnage royalty for the United Mine Workers' health and welfare fund even if it meant another strike, because the levy is "economic blackmail." Forney Johnstone, counsel for the National Coal Association, said that "Congress should understand that a large proportion of the coal industry, if not the entire industry, on relinquishment of federal control, cannot agree voluntarily to a collective pooling of the mine labor of two thousand unrelated mines for the levy of a tonnage tax by the mine workers for any such blind pool." The association is not asking Congress to declare such benefits illegal if agreed to in "wholly voluntary contracts" but does ask that operators "not be coerced with the sanction of Congress."

Proposed Erection of Betatrons for Treatment of Cancer

The U. S. Bureau of Standards has announced that plans are completed for construction of two betatrons which will make Washington the national center for testing x-ray equipment. Other functions of the betatrons will be the treatment of cancer and the protection of x-ray technicians. The announcement stated that, as a medical tool, the betatron can provide x-rays suitable for cancer treatment under conditions long dreamed of but never before realized.

Plans Approved for Veterans Hospital in Arlington

Plans for the seven hundred and fifty bed veterans' hospital to be erected in Arlington, Va., have been approved by Veterans Administration medical and construction chiefs. The hospital will be nine and a half stories high but will not compete with the beauty of the Lincoln Memorial across the river. The structure will enable two thirds of its occupants to view the United States capital. The hospital will not be ready for twenty-seven months.

Supply of Physicians in Washington

The Medical Society of the District of Columbia reports that Washington has an estimated 1,500 physicians in active practice in the metropolitan area, or about one physician to 900 persons. The safety ratio is about one doctor to a thousand of population. Executive Secretary Wiprud also reports that the office space problem is almost solved, except in the downtown area.

Coming Medical Meetings

Alabama, Medical Association of the State of, Birmingham, April 15-17. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Academy of Pediatrics, Pittsburgh, Feb. 24-27. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Anatomists, Montreal, Canada, April 3-5. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association for the Study of Goiter, Atlanta, Ga., April 3-5. Dr. Thomas C. Davison, 478 Peachtree St., N. E., Atlanta 3, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, February 27. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Secretary.

Arkansas Medical Society, Little Rock, April 17-19. Dr. William R. Brocksher, 602 Garrison Ave., Fort Smith, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 17-20. Dr. Glenn D. Earlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Iowa State Medical Society, Des Moines, April 16-18. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book-Cadillac Hotel, March 12-14. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Missouri State Medical Association, Kansas City, March 30-April 2. Mr. Thomas R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Executive Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Northern Tri-State Medical Association, Detroit, April 8. Dr. John L. Stifel, 232 Michigan St., Toledo 2, Ohio, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Southwest Allergy Forum, Shreveport, La., March 31-April 1. Dr. Sim Hulsey, 505 Medical Arts Bldg., Fort Worth, Texas, Secretary.

Tennessee State Medical Association, Memphis, April 8-10. Dr. W. M. Hardy, 706 Church St., Nashville 3, Secretary.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National Science Foundation

The creation of a **National Science Foundation** is proposed by S. 526, introduced by Senator Smith, New Jersey, for himself and Senator Cordon, Oregon, Senator Revercomb, West Virginia, Senator Saltonstall, Massachusetts, Senator Magnuson, Washington, and Senator Fulbright, Arkansas. There will be forty-eight members of the foundation to be appointed by the President, who is requested in making appointments to give due consideration to any recommendations submitted to him by the National Academy of Sciences or by any other scientific or educational organizations. The foundation will have a chief executive officer, to be known as the director of the foundation, and he will be appointed by its executive committee, with the approval of a majority of the members of the foundation. Within the foundation there will be a division of national defense, a division of medical research, which will administer programs of the foundation relating to research in the medical sciences, a division of mathematical, physical and engineering sciences, a division of biological sciences and a division of scientific personnel and education.

Another bill has been introduced in the Senate proposing to create a **National Science Foundation,** S. 525, by Senator Thomas, Utah.

National Health Act

Senator Taft, Ohio, for himself and Senator Smith, New Jersey, Senator Ball, Minnesota, and Senator Donnell, Missouri, introduced S. 545, a bill proposing to enact the **"National Health Act of 1947."** A discussion of this bill was published as an editorial in The Journal, February 15.

Department of Health, Education and Security

The Senate Committee on Expenditures in the Executive Departments has announced that a ***preliminary hearing*** will be held on the **Fulbright-Taft bill, S. 140,** on February 28. The hearing, it is understood, will be preliminary in nature only and the committee will thereafter determine whether additional hearings are to be held.

Miscellaneous

A bill introduced by Representative Rees, Kansas, H. R. 1714, proposes to exclude certain interns, student nurses and other student-employees of hospitals of the federal government from the classification act and other laws relating to **compensation and benefits of federal employees.**

The federal security administrator would be authorized by S. 497, introduced by Senator Langer, North Dakota, to make **loans to institutions** for the purpose of financing the construction of domiciliary facilities for the aged and the blind.

Representative Boggs, Louisiana, proposes by H. R. 1811 to provide **dispensary treatment and hospitalization** in army and navy hospitals for retired enlisted men of the Army, Navy, Marine Corps and Coast Guard.

H. R. 1438, introduced by Representative Cellar, New York, proposes to bring within the purview of the **Social Security Act** employment in nonproprietary hospitals.

STATE LEGISLATION

California

Bills Introduced.—A. 1034, to amend the business and professions code, proposes that the trained attendants shall have three months, rather than one year practical experience in a reputable hospital or sanatorium. A. 1057 and S. 485, to amend the business and professions code, propose the creation of a **Board of Examiners of Trained Attendants** and define the acts which trained attendants may perform. A. 1078, to amend the health and safety code, proposes a law for the licensing, inspection, regulation and supervision of **public and private hospitals** within the state. A. 1205, to amend the business and professions code, proposes to authorize the issuance of an **herb practitioner's certificate** and to authorize the Board of Medical Examiners to establish standards, qualifications and procedure for the licensing of such practitioners. S. 511, to amend the health and safety code, proposes that any physician performing a ***postmortem examination*** for a coroner shall be a physician and surgeon trained in pathology. S. 512, to amend the health and safety code relating to standards of hospitals operated by local hospital districts, proposes that such **hospitals shall maintain minimum standards** established and promulgated by the Council on Medical Education and Hospitals of the American Medical Association or by the American College of Surgeons. S. 539, to amend the business and professions code, proposes to **require all practitioners of medicine,** on written request from a person he has attended in his professional capacity or from some duly authorized representative, to execute and issue a certificate of the facts of illness, injury, death or other facts concerning the patient.

Connecticut

Bills Introduced.—H. 381, to amend the **law relating to naturopathy,** proposes to prohibit the issuance of licenses to practice naturopathy in Connecticut simply on the basis of licensure in another state without the applicant meeting the qualifications set forth by the Connecticut law. H. 392, to amend the **law relating to medicine and surgery,** proposes that persons practicing the massage method or Swedish movement method be no longer exempt from the medical practice act. S. 64 proposes to add **thyroid** to the list of drugs which may be sold only on a written prescription *signed by a member of the medical, dental or veterinary profession* licensed by law to administer such drug. S. 133, to amend the **law relating to osteopathy,** proposes to establish higher minimum requirements and more rigid supervision of the practice of osteopathy in the state.

Idaho

Bills Introduced.—H. 141 proposes to add **cancer** to the list of diseases which a physician must immediately report to the department of public health. H. 141 proposes to limit the sale of **barbituric acid** or compounds to sale on a prescription signed by a person licensed to prescribe and administer barbiturates. S. 57 proposes an act to require the **licensing,** inspecting and regulating of all **hospitals** within the state. S. 67 proposes the enactment of a physiotherapy-naturopathic practice act and the creation of a **state board of physiotherapy and naturopathy examiners.** Under the proposal naturopathy would include physiotherapy and massage, and the practice of naturopathy is defined as including "diagnosis, and the employment of botanicals, diets, dietary adjuvants and organic substances used in the correction of functional disabilities and faulty blood chemistry, electrotherapy, hydrotherapy and physical therapy, and manual manipulations. It does not include the practice of obstetrics or surgery that penetrates subcutaneous tissues of the body, or the use of the hypodermic needle for injection purposes, manufactured chemical medicines, narcotics and opiates as defined in the Federal Narcotics Act, radium or x-rays for treatment." The practice of physiotherapy "includes physiotherapeutic modalities now recognized or which may be developed and become recognized through use, and the employment of dietary adjuvants, hydrotherapy and manual manipulations. It does not include diagnosis, the practice of obstetrics or surgery that penetrates subcutaneous tissues of the body, or the use of the hypodermic needle for injection purposes, manufactured chemical medicines, narcotics and opiates as defined in the Federal Narcotics Act, radium or x-rays for treatment." The practice of massage "includes the use of the hands as a means for the correction of any physical disability, and the employment of dietary adjuvants and bulk diet as part of a recognized method of physical conditioning, hydrotherapy with the exception of irrigations, and manual manipulations. It does not include diagnosis, the practice of obstetrics or surgery that penetrates subcutaneous tissues of the body, or the use of the hypodermic needle for injunction purposes, manufactured chemical medicines, narcotics or opiates as defined in the Federal Narcotics Act, radium or x-rays for treatment."

Indiana

Bill Introduced.—H. 174 proposes the creation of a **state board of chiropractic examiners** and defines chiropractic to be "the science of locating and the removing of nerve interference according to chiropractic principles."

Bill Pased.—S. 1, to amend the law relating to **hospital surveys,** passed the senate January 27. It proposes to appoint the state board of health as the state agency to coöperate with the federal government in the construction of hospitals within the state and proposes to add to the hospital survey law a new section defining the terms "hospital," "public health center" and "nonprofit hospital."

Kansas

Bills Introduced.—H. 67 proposes the enactment of a law providing for the licensing, inspection and regulation of **hospitals** and the appointment of a hospital advisory council. H. 102 proposes to require all persons applying for a **marriage license** to present a certificate signed by a physician legally qualified under the laws of the state of Kansas or of the state in which he is practicing that the applicant is not infected with syphilis in such a stage as to make it communicable to a marital partner. H. 115 proposes to require **all physicians to report** to the state board of health within five days the name, age and address of every person diagnosed as a case of epilepsy or similar disorders characterized by lapses of consciousness.

Maryland

Bills Introduced.—H. 148, to amend the **law relating to marriage,** proposes that applicants for a marriage license shall produce a certificate signed by a duly licensed physician showing that the applicant is *not* infected with syphilis in a stage whereby it may become communicable. S. 162 proposes to require physicians, osteopaths and other professional workers to **renew their licenses** annually by payment of a $10 annual registration fee.

Montana

Bills Introduced.—H. 149 proposes a law for the establishment of a Montana cash sickness and disability **compensation system.** H. 235 proposes a law for the licensing and regulating of **hospitals** within the state. H. 236 proposes the enactment of a Montana Hospital Survey and Construction Act requiring a **survey of hospital and health facilities** in the state, a program of construction for additional needed facilities, the appointment of an advisory hospital council and the necessary cooperation for the receiving of federal funds to aid in the construction of such additional needed facilities as the program may require.

New Mexico

Bills Introduced.—H. 45 proposes to require all applicants for a **marriage license** *to present a certificate from a* physician and surgeon duly licensed to practice medicine and surgery in the state of New Mexico showing that such applicant is not, in the opinion of the physician, infected with syphilis in such a stage that it may become communicable to the marriage partner. S. 74 proposes to require the licensing, inspection and regulation of **hospitals** and related institutions within the state.

New York

Bills Introduced.—A. 801, to amend the public health law, proposes to require every physician to give immediate notice to the health officer of every case of **infantile paralysis** under his care. A. 861, to amend the law relating to the issuance of **marriage licenses**, proposes to require every applicant to submit a statement from a physician showing that a chest x-ray examination and laboratory tests for the discovery of tuberculosis have been made and that the applicant is not suffering from tuberculosis in a communicable stage. A. 1036, to amend the education law proposes to prohibit physicians from **advertising in newspapers.**

Oregon

Bills Introduced.—S 77 proposes the repeal of existing laws requiring the **licensing of maternity hospitals** and certain other types of institutions and sanatoriums and the enactment of a new law requiring the licensing, inspecting and regulating of all hospitals and related institutions within the state. S. 189 proposes to increase the **annual registration fee of** physicians from $5 to $10.

Rhode Island

Bill Introduced.—H. 612 proposes the enactment of a hospital survey and construction act requiring a **survey of hospital facilities** in the state and the preparation of a program for the construction of additional needed facilities. The proposal would also require the appointment of an advisory hospital council and would authorize the director of the state department of health to apply to the Surgeon General for federal funds to assist in either the survey or the construction of new facilities.

South Dakota

Bill Introduced.—H. 50 proposes the enactment of a South Dakota Hospital Survey and Construction Act requiring a survey of existing hospital facilities and a program for the construction of necessary additional facilities. It also proposes to provide compliance with the requirements of the federal hospital survey and construction act.

Bill Passed.—H. 18 passed the House January 29. It proposes rules and regulations for the licensing of **chiropractic hospitals,** sanatoriums or related institutions by the board of chiropractic examiners.

Bill Enacted.—S. 32 was approved Jan. 24, 1947. It provides that any person who served in World War II and received an honorable discharge therefrom, and who at the time of induction was a regularly licensed practitioner of a profession in the state, and whose status as such practitioner was lost during the time he was in service, **shall be restored and reinstated** to the status held at the time of his induction without requiring him to submit to any examination therefor.

Tennessee

Bills Introduced.—H. 232 proposes the enactment of a law providing for the regulating and **licensing of all hospitals** within the state. H. 234 proposes the enactment of a **"State Licensing Board for the Healing Arts"** and defines healing art as "offering or undertaking to diagnose, treat, operate on or prescribe for any human pain, injury, disease, deformity or physical or mental condition." Any person desiring to practice any specific branch of the healing art would be required to obtain a license from this new board after having passed the specific examination required of the specific examining board. H. 235 proposes the enactment of a **state hospital survey** and construction act requiring a survey of existing hospitals and a program for the construction of needed additional facilities. The proposal also provides for compliance with the requirements of the federal hospital survey and construction act and regulations thereunder.

Texas

Bills Introduced.—H. 160, to amend the medical practice act and a complementary section of the penal code proposes to exempt therefrom **naturopathic physicians,** duly licensed under the laws of the state, who confine their practice to naturopathy as defined by the statutes. H. 225 proposes to limit the sale of paregoric to prescription of a physician duly licensed to practice medicine in the state. S. 79 proposes the creation of a Texas **Board of Chiropractic Examiners** and defines chiropractic to be "the employment of objective or subjective means, without use of drugs or surgery, for the purpose of ascertaining the alinement of the vertebrae of the human spine, and the practice of adjusting the vertebrae by hand to correct any subluxation or misalinement thereof." S. 115, to amend the medical practice act, proposes to eliminate provisions which might be interpreted as relating to **cult practitioners** and to make certain other changes. S. 120, to amend the penal code, proposes to make it unlawful for any physician or other practitioner of the art of healing to **advertise special skills,** definite prices or the use of superior qualities of medicine, material, devices, etc., in the performance of professional service.

Utah

Bills Introduced.—H. 152 proposes the enactment of a **basic science law,** the basic sciences being stated as anatomy, physiology, pathology, bacteriology and chemistry. S. 151 proposes the enactment of a **state hospital survey** and construction act requiring a survey of all hospital and public health center facilities in the state and of the preparation of a program for the construction of additional needed facilities. The proposal would require the appointment of an advisory hospital council and would authorize the commissioner of the state department of health to apply for federal funds for assistance in either the survey or the construction program.

Virginia

Bills Enacted.—S. 27-X has become chapter 15 of the Laws of 1947. It provides a **hospital licensing and inspecting law** but exempts therefrom hospitals operated *for the practice of the religious tenets* of any church in the ministration to the sick and suffering by mental or spiritual means without the use of any drug or material remedy, provided the statutes or regulations on sanitation are complied with. S. 28-X has become chapter 14 of the Laws of 1947. It provides for the establishment within the Department of Health of a **Division of Hospital Survey** and Construction to make a survey of existing hospitals, develop a state plan for the construction of nonprofit hospitals in the state, etc. The new law provides for the appointment of a hospital advisory council and authorizes the commissioner of the state department of health to apply for federal funds to assist in carrying out the survey and planning activities contemplated by the law and to receive federal funds on behalf of applicants and transmit them to such applicants. S. 31-X has become chapter 16 of the Laws of 1947. It provides a **hospital licensing law** for hospitals caring for insane, epileptic or feebleminded persons or persons addicted to the intemperate use of narcotic drugs, alcohol or other stimulants.

Washington

***Bills Introduced.**—H. 57 proposes the creation of* **basic science examining committees** for the practice of medicine and surgery, osteopathy, osteopathy and surgery, chiropractic and drugless therapeutics. The duty of each basic science examining committee would be to conduct and assist in conducting examinations in the basic sciences of all persons applying for licenses or certificates to practice the particular profession for which a license is sought. H. 77 proposes the creation of an examining board for **the practice of massotherapy** and defines massotherapy as "the method, art or science of treating the human body for hygienic or remedial purposes to maintain health and to establish a normal condition of the body, and shall include all massage manipulations, passive and active remedial gymnastics and relaxing movements and manipulations with the hands or with any other agency or instrumentality designed to accomplish massage manipulations or gymnastics to promote physiological action to bring about a normal condition of health and restore bodily functions to a normal condition." The proposal also provides for supplemental licenses to practice hydrotherapy and physical therapy. S. 78 proposes the creation of a state **board of naturopathic examiners** and defines naturopathy as the practice and procedure taught and recognized by regular schools or colleges of naturopathy recognized by the Washington State Naturopathic Association, Inc.

West Virginia

***Bills Introduced.**—H. 81, to amend the law relating to medical and* hospital service corporations, proposes to authorize such corporations to **promote and encourage reciprocity with** similar plans both within and without the state. S. 188, to amend the medical practice act section relating to exemptions therefrom, proposes to exempt from the provisions of the act persons practicing the **religious tenets of the church** in the ministration to the sick or suffering by mental or spiritual means.

Bill Passed.—H. 50 passed the House January 31. It proposes regulations for the supervision and **management of state institutions** for the care of persons suffering from tuberculosis and proposes to make it mandatory for every physician practicing in the state to report in writing to the board of control the name, age, sex, race, home address and type of disease of every person having tuberculosis who comes under his observation or care, within forty-eight hours after the discovery of this condition.

Wisconsin

Bills Introduced.—S. 60, to amend the law relating to **scientific experimentation and** research, purposes that animals may be used for scientific experimentation and research if not subjected to cruelty or torture. S. 104 proposes regulations for the licensing, inspecting and regulating **hospitals** within the state. S. 105 proposes the enactment of a **state hospital survey** and construction act, requiring a survey of hospitals and health facilities in the state and the preparation of a program for the construction of additional needed facilities. The proposal would require the appointment of an advisory hospital council and would authorize the state board of health to apply for and receive federal funds to assist in such survey or construction program.

Wyoming

Bills Introduced.—H. 63 proposes amendments to the medical practice act which would require the appointment of **an osteopath on the examining board** and the licensing of applicants to practice osteopathy, which is defined to mean "the treatment of human ailments, diseases or infirmities by mechanotherapy, or by any means or method other than surgery or drugs." The amendments also would permit use of the injunctive process to restrain the unlicensed practice of medicine, surgery or osteopathy. H. 74 proposes the creation of a **board of naturopathic examiners.** Section 4 would provide "The Definition of Naturopathy shall be as approved by an Act of Congress, Feb. 27, 1929, and including any and all rulings of the Supreme Court or Attorney General hereafter, which hereafter shall comprehend and embrace and be composed of the following act and practices and usages of the physiological and mechanical and material sciences of healing, as follows: Iridology, diagnosis and the practice of physiological, mechanical and material sciences of healing; the physiological and mechanical sciences, such as the mechanotherapy, articular manipulation, corrective and orthopedic gymnastics, naturotherapy, psychotherapy, hydro-therapy and mineral baths, electrotherapy, thermotherapy, radiotherapy, phototherapy, chromotherapy, vibrotherapy, thalamotherapy and orificial dilation and other stimulation of the sympathetic nervous system through the orifices, and dietetics, which shall include the use of foods of such biochemical tissue building products and cell salts as are found in the normal body; and the use of vegetal oils and dehydrated and pulverized fruits, flowers, seeds, barks, herbs, roots and vegetables uncompounded and used in their natural state; and herein to include the practice of such other sciences as the practice of obstetrics and minor surgery in accordance with the teachings in the Naturopathic Schools and

GOVERNMENT SERVICES

ARMY

PACIFIC MOSQUITOES REACH THIS COUNTRY IN TIRES

In a routine Public Health Service quarantine inspection of a cargo ship arriving at Los Angeles from New Guinea, a sanitary inspector discovered that mosquitoes had been breeding in fresh water contained in about half of the nearly 9,000 tires which were being returned to the United States from combat areas. The tires contained water varying in amount from one cup to five gallons per tire and it was estimated that the average tire examined containing water contained also from twenty to thirty larvae. Some of the mosquitoes were the kind that carry dengue fever and filariasis in their native Pacific Islands. The ship before docking was thoroughly sprayed with freon-pyrethrum aerosol, and later many dead adult mosquitoes were found. In eleven subsequent shipments of tires water was found in eight and mosquitoes were found breeding in three of the shipments. All material which contained water, it is reported, was routinely treated with a mosquito destroying solution.

SURVEY OF FOOD NEEDS OF JAPAN

The War Department announced on January 23 that a mission comprising seven members would leave the United States for Japan about February 1 to study the needs for civilian feeding of Japan, Korea and Ryukyus for food exports from the United States. Heading the group is Col. Raymond L. Harrison, Department of Agriculture; other members are Capt. Tracy B. Kittredge, U.S.N., detailed from the Office of the Secretary of the Navy to the Office of the Secretary of War; Mr. Nathan Koenig, executive assistant to the Secretary of Agriculture; Mr. Kenneth B. Jacob, principal chemist, department of Agriculture; Mr. Roswell H. Whitman, associate chief, Division of Japanese-Korean Economic Affairs, Department of State; W. Hallam Tuck, consultant to the Secretary of War, and Col. Joseph W. Scobey, chief, International Branch, Supply Group, War Department General Staff.

LIQUID OXYGEN CONVERTER FOR BREATHING PURPOSES

Army Air Forces disclosed on February 10 the development of a liquid oxygen converter for breathing purposes which has distinct advantages over other converters developed (and some found unpractical) over a period of many years of experimentation. The new converter is simple to operate and greatly reduces the weight and space requirements of oxygen equipment now in use. The National Bureau of Standards and the Bendix Aviation Corporation assisted the Army Air Forces in developing the new converter. It has been subjected to various laboratory tests and has been flight tested up to an altitude of 40,000 feet, using a crew of eight men, and in all experiments the equipment performed satisfactorily. The liquid system contains 750 cubic feet of oxygen (after conversion to the gaseous stage) in one unit, which occupies only 5 cubic feet of space and weighs 130 pounds, whereas the low pressure system now in use occupies 30 cubic feet of the plane's interior with eighteen large tanks holding 522 cubic feet of oxygen and weighing a total of 412 pounds. The liquid unit therefore would save 67 per cent of the weight and increase the available oxygen by 45 per cent, while the cubage consumed is about one-sixth that of the present system. The converter requires no source of heat other than ambient temperature. The Massachusetts Institute of Technology is conducting further experiments to find better methods for storage and handling of the liquid oxygen, which must be under sufficient pressure in storage to prevent evaporation.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Joseph G. Kostrubala

The Army Commendation Ribbon has been awarded to Lieut. Col. Joseph G. Kostrubala, M. C., A. U. S., of Chicago, who was addressed in these words in a citation signed by the Surgeon General: During World War II the Medical Department carried out its mission with outstanding success. This achievement was made possible only through the combined efforts of all Medical Department personnel. Your service with the Medical Department has been exceptional when compared with others of the same grade of similar position, and I wish to commend you for your outstanding contribution as assistant chief, plastic surgery section, William Beaumont General Hospital, El Paso, Texas, from July 1, 1945 to April 15, 1946. Dr. Kostrubala graduated from Northwestern University Medical School in 1937 and entered the military service Aug. 16, 1942.

Lieutenant Colonel Arie C. van Ravenswaay

The Legion of Merit has been awarded to Lieut. Col. Arie C. van Ravenswaay, M. C., A. U. S., of Boonville, Mo., who was chief of the Special Projects Branch, Office of the Air Surgeon, Headquarters, Army Air Forces, from December 1943 to September 1945. The citation states that he administered many projects related to the preservation of the health of Army Air Forces personnel. Colonel van Ravenswaay's many advances in medical science have been of inestimable value and reflect great credit on himself and on the armed forces of the United States. Dr. van Ravenswaay graduated from Washington University School of Medicine in 1932 and entered the military service on Aug. 21, 1942.

Major William Leifer

The Legion of Merit has been awarded to Major William Leifer, M. C., A. U. S., of New York. The citation states that he distinguished himself as chief of Penicillin Research Project at Regional Hospital, Fort Bragg, North Carolina, from July 1943 to September 1945. His contribution in the furtherance of studies pertaining to penicillin as a measure for combating the effects of certain diseases among personnel of the armed forces contributed materially to the success of the National Research Council. Major Leifer's attainments reflect credit on himself and on the Army Medical Department. Dr. Leifer graduated from New York University College of Medicine in 1925 and entered military service May 30, 1942.

Major James V. Luck

The Legion of Merit was recently awarded to (formerly) Major James V. Luck, M. C., A. U. S., of Los Angeles, who served as an orthopedic surgeon, Santa Ana Army Air Base from January 1943 to September 1944, and as chief, orthopedic surgery section, Army Air Forces Regional Hospital, Chanute Field, from September 1944 to January 1946. The citation states that he made outstanding contributions to military and civilian orthopedic surgery. Major Luck's unusual professional ability and his brilliant attainments reflect the highest credit on himself and the armed forces of the United States. Dr. Luck graduated from St. Louis University School of Medicine in 1931 and entered the service in November 1942.

MISCELLANEOUS

SALE OF PORTABLE X-RAY UNITS

The War Assets Administration has 200 portable x-ray units for sale at St. Louis. Physicians who are veterans have certain priority rights in purchasing this equipment. They should communicate with the War Assets Administration, Regional Office, 505 North 7th Street, St. Louis 1.

NAVY

NEED RESERVE MEDICAL OFFICERS

Headquarters of naval air reserve training is at the Naval Air Station, Glenview, Ill., and within that command are sixteen major naval air stations and six training units. Each of the naval air stations requires two full time medical officers, one of whom must be a flight surgeon. Each of the training units requires one full time medical officer who must be a flight surgeon. In addition, medical officers are needed for part time duty with combat units of the air reserve. The organized reserve units usually report twice a month on weekends and receive pay which, over a period of a year, amounts to about two months of full time active duty pay. Reserve medical officers and pharmacists interested in active duty of this kind should write to the Bureau of Naval Personnel via the chief of Naval Air Reserve Training, Naval Air Station, Glenview, Ill. Personnel are desired in ranks not above that of commander in the medical corps. Every effort will be made to continue officers qualified for this service in the assignments consistent with the needs of the service. Government quarters are available at many of the major naval air stations.

NAVY AWARDS AND COMMENDATIONS

Captain James R. Fulton

The Legion of Merit has been awarded to Capt. James R. Fulton (MC), U.S.N., of Bremerton, Wash., for exceptionally meritorious conduct in the performance of outstanding service as senior medical officer of the U. S. S. *Bountiful* from January to December 1944 during the invasion of Saipan, Guam, Peleliu and the Philippine Islands. The citation calls attention to the facts that he organized and indoctrinated his staff to render every possible emergency and surgical aid to the sick and wounded. His professional skill as a surgeon and consultant contributed to the saving of many lives. His leadership and devotion to duty were directly responsible for the extremely low mortality rate among the injured received for treatment. His performance of duty was outstanding and his conduct was at all times in keeping with the highest traditions of the United States Naval Service. Dr. Fulton is a graduate from Harvard Medical School in 1925 and entered military service June 22, 1925.

PUBLIC HEALTH SERVICE

REGULATIONS FOR HOSPITAL SURVEY AND CONSTRUCTION ACT

The Hospital Survey and Construction Act, enacted Aug. 13, 1946, permits appropriations up to $3,000,000 to assist states in surveying and planning their hospital needs, and $75,000,000 annually for the next five years to assist in the construction of hospitals and health centers. For administration and surveys $2,350,000 has been appropriated. No construction money has yet been appropriated, but funds for this purpose will be requested at the present session of Congress. Administration of the hospital program is left primarily to the states, but the law specifies that regulations shall be prescribed by the Surgeon General of the United States Public Health Service and approved by the Federal Security Administrator and the Federal Hospital Council. The newly issued regulations cover type, size and distribution of hospitals, priority to be given to projects, general standards of construction and equipment, and state administration methods. Provision also is made to assure services to persons unable to pay. The number of general hospital beds to be distributed according to the act among base, intermediate and urban areas ranges from 4.5 to 5.5 beds per thousand of population, depending on state population density. Regulations further qualify distribution from 2.5 beds per thousand of population in rural areas to 5.5 beds per thousand in base areas. Should the combined number of beds allowed in various areas of a state be less than the total allowed for the entire state, remaining beds are to be distributed at the discretion of the state, with special consideration for hospitals serving rural areas and communities with small financial resources.

Regulations follow the law on distribution of beds in tuberculosis, mental and chronic disease hospitals. Maximum beds for tuberculosis patients will be 2.5 times the average annual deaths from tuberculosis in the state over the five year period from 1940 through 1944, for mental patients, 5 per thousand of population and for chronic disease patients 2 per thousand of population. The regulations stipulate that building of these hospitals shall be in centers of population and in proximity to general hospitals whenever practical.

The number of public health centers is not to exceed one for each 30,000 of population except in states with fewer than 12 persons per square mile, where the number of centers is not to be more than one for each 20,000 of population. Each state has the authority to distribute these centers to conform to its individual organization of local health units.

Since the goal of the program is to provide hospitals where they are most needed, construction funds will be granted according to priorities indicated by each state in its overall construction plan. Both the law and the regulations, however, establish principles to be followed in determining the priority to be given hospital projects. The law provides for the granting of priorities to general hospitals in rural areas and in localities where population groups are less adequately served because of race, creed or color. Public health centers in rural areas also will receive preference. Regulations further specify that each state, as far as practical, shall develop its program in accordance with the proportionate need for each of the five types of hospitals authorized in the act: general, mental, tuberculosis, chronic and health centers. For all types of hospitals, priority is to be given to new construction and additions to existing facilities rather than to replacements.

Standards of construction and equipment which the regulations establish include minimum requirements necessary to insure properly planned and well constructed hospital buildings. The standards relate to choice of site, type of architecture, construction, sanitation and general building regulations.

Regulations call for assurance from applicants for construction funds that hospitals built with federal aid under this act shall be open to every one. The regulations provide that hospitals under the plan must be available without discrimination on account of race, creed or color. In areas where separate hospital facilities are provided for separate population groups an exception may be made, but only if the plan makes equitable provision for facilities and services of like quality for all such groups. "Equitable provision" is defined as equal to the proportion of the separate population groups in the total population of the area. They also specify that a state shall not include in its construction program facilities for a separate population group beyond what are needed for adequate hospital care.

The regulations also call for assurance from applicants that a reasonable amount of free patient care will be given. In determining what constitutes a "reasonable amount" the state considers conditions in the area to be served, including free care already available. This provision may be waived by the Surgeon General when it is not financially feasible.

Regulations include general methods of administration of state construction plans by state agencies designated to carry out hospital programs. This section covers development of the state program, processing of applications and the conditions required for their approval, the manner of making construction payments and other fiscal matters.

A base area is described as one containing either a university teaching hospital or a population of 100,000 with a large general hospital. The law is the basis for the definition of a hospital, which includes not only hospitals and health centers but related facilities such as laboratories, outpatient departments, nurses' homes and training schools and central service facilities operated in connection with hospitals. Federal hospitals and institutions furnishing primarily domiciliary care are excluded from financial aid through this act. A limited number of reprints of the regulations will be available from the Public Health Service.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Personal—The new director of the state health department's Division of tuberculosis control is Dr James M Freeze, U S Public Health Service, who succeeds Dr N H DeJanney, Alabama City, resigned Dr Freeze comes from Bethesda, Md, where he has been doing graduate work in the U S Public Health Service office

Dr. Foley Named Professor of Anatomy.—Dr James D Foley has been appointed chairman and professor of anatomy at the Medical College of Alabama Birmingham Dr Foley, ormerly of Tulane University of Louisiana School of Medicine, New Orleans, joined the faculty of the medical college in 1945 when the Alabama School of Basic Medical Science was made part of the four year medical college of Alabama Dr Foley received his B S degree from Oregon State College and his Ph D from the University of Wisconsin His research has dealt chiefly with the anatomy of the nervous system

CALIFORNIA

Society News.—The Trudeau Society of Los Angeles, which constitutes the Tuberculosis Section of the Los Angeles County Medical Association, has elected as officers for 1947 Drs Edward Kupka, Los Angeles, president, Joseph L Robinson, Olive View, vice president, and Arthur E T Rogers, Olive View, secretary treasurer

Annual Reginald Knight Smith Lecture.—Mount Zion Hospital, San Francisco, presented its annual Reginald Knight Smith Lecture February 13 The lecturer was Dr William Dameshek professor of clinical medicine, Tufts College Medical School, Boston and his subject "Disorders of the Spleen with Particular Reference to Hypersplenism"

FLORIDA

School Health Program—The state board of health plans to conduct a special school health examination and immunization program which will reach 40,000 children before July 1 A special grant of $70 000 from the federal Children's Bureau to conduct the program was obtained by Dr Wilson T Sowder, Jacksonville, state health officer Twenty-five young doctors under the supervision of Dr Grace Hardy, pediatrician, have consented to enter the field Defective sight, hearing, posture and mild nutrition deficiencies which show up in the skin will be particular objectives of the campaign Cases will be referred to private physicians and to the crippled children's commission Most of the work is to be carried on in counties where county health department personnel is inadequate

ILLINOIS

Campaign to Improve Mental Care—The Illinois Society for Mental Hygiene has named a committee to spearhead a statewide campaign to raise the state mental hospitals to the minimum standards for adequate treatment and care of patients, Dr Rudolph G Novick, medical director of the society, has announced Illinois hospitals, he says, fall short of the minimum standards of the American Psychiatric Association by more than 150 doctors, 1,220 nurses and 1,358 attendants besides deficiencies in social workers and therapists On the committee are Ronald P Boardman, president of the society, Drs John J. Madden, Maxwell Gitelson and George J Mohr, Mrs Thomas A Connors, Mrs Sarah B Schaar and Frank H Woods Jr

Program in Speech and Hearing Rehabilitation—A research and clinical program in speech and hearing rehabilitation has been opened by the University of Illinois College of Medicine Chicago, under the direction of Herbert Koepp-Baker, Ph D, formerly director of the speech and hearing clinic at Pennsylvania State College The work will be supervised by Dr Francis L Lederer, head of the otolaryngology department and chief of that service in the Eye and Ear Infirmary Dr Koepp Baker will also direct the new speech and rehabilitation division of the Illinois Eye and Ear Infirmary. The department will immediately provide instruction and clinical experience in this field for medical students, physicians and persons in closely correlated nonmedical branches of speech education Instruction will be on a graduate and postgraduate level.

Evanston Fluorine Research Project.—After some three years of planning, a program was activated February 17 whereby 1 part of fluorine will be added to each million parts of the water supply of Evanston in a research project which it is hoped will limit or check tooth decay in Evanston and Skokie The examination of 4,400 school children in these communities in two groups, 7 to 9 years of age, and 12 through 14, was completed February 7 The younger group will be reexamined within a year and the older group after two years The program, based on a survey made several years ago by the U S Public Health Service, is sponsored by the Evanston Board of Health, the State Dental Department and the Zoller Dental Clinic of the University of Chicago The survey is said to have revealed that children in Evanston and some other suburbs using Lake Michigan water, which is fluorine free, suffered almost three times more tooth decay than children in certain inland cities where the water contains a minute trace of fluorine The commissioner of health of Evanston, Dr Winston H Tucker who is working with Dr J Roy Blayney, director of the Zoller Clinic, on this research program said that it remains to be seen whether artificially added fluorine is as effective as that found as a natural element in drinking water The fluorine solution to be added is tasteless, colorless and odorless

Chicago

Rabies Warning.—Cases of rabies are on the increase in Chicago according to Dr Edward A Piszczek, county health director Within the first three weeks of January 20 cases of rabies in dogs were reported in Cook County, 10 of them in Chicago, a large number for the winter season, Dr Piszczek said

Alcohol and the Psychiatric Problem—Dr Vladimir G Urse, superintendent of Cook County Psychopathic Hospital, told the Illinois County and Probate Judges association at their recent convention in Chicago that today 1 out of every 4 patients at Psychopathic Hospital is an alcoholic problem as compared to 16 per cent thirty years ago and 21 per cent five years ago The judges are concerned over the flooding of mental institutions with alcoholic addicts

The McArthur and Hektoen Lectures—The twenty-third Lewis Linn McArthur Lecture of the Frank Billings Foundation will be delivered at the Palmer House Friday, February 28 at 8 p m Dr Robert H F Elliott Jr, department of surgery, Columbia University College of Physicians and Surgeons New York, will speak on "A Revaluation of Splenectomy in Thrombocytopenic Purpura Based on a Twenty-Seven Year Combined Clinic Follow-Up" Dr Herbert M Evans director Institute of Experimental Biology, University of California Berkeley, will deliver the twenty third Ludvig Hektoen Lecture of the foundation at the Palmer House March 28 at 8 p m His subject will be "The Internal Secretions of the Pituitary Body"

KANSAS

Public Health Training Center—The Topeka City-Shawnee County Training Center for public health workers, 300 West Eighth Street, has opened with public health employees as the first class of trainees Teaching personnel have been assigned to the center by the U S Public Health Service to take responsibility for the first course Sanitarians from health departments in North and South Dakota, Nebraska, Minnesota, Iowa and Missouri as well as Kansas are attending Director of the training center, said to be the second of its kind in the country, is Dr David D Carr It is sponsored by the Kansas State Board of Health, with the U S Public Health service cooperating

LOUISIANA

Rudolph Matas Gives 50 Year Files to Library.—The Matas Library of the Tulane University of Louisiana School of Medicine, New Orleans, has received files of the Italian medical journal *Policlinico* covering the fifty year period preceding World War II They are the gift of Dr Rudolph Matas, professor emeritus of general and clinical surgery, on the occasion of his eighty-sixth birthday

Tulane Offers Degree in Public Health—The departments of Tropical Medicine and Preventive Medicine of the Tulane University of Louisiana School of Medicine, New Orleans, have combined to form a new department of Tropical Medicine and Public Health The enlarged department will consist of three units clinical tropical medicine, parasitology and public health Plans are under way to offer a course which will lead to a combined degree in tropical medicine and public health. The only school which now offers such a combined degree is the London School of Hygiene and Tropical Medicine, London, England. There are now only eight schools in this country offering training in public health. Plans are also being made for the new department to take over the University Student Health Service, with greatly enlarged facilities. This will involve the establishment of a university infirmary for all nonresident students. The new health service will act as a training center for public health instruction. The new department will be headed by Dr. William A. Sodeman, who has been head of the Department of Preventive Medicine since 1941. Dr. Sodeman is now carrying on special clinical studies at the School of Tropical Medicine in Puerto Rico and will later visit Venezuela and Panama, where he will study prevalent tropical diseases and methods for their control. The merger of the two departments will become effective when he returns.

MICHIGAN

Personal.—Dr. Max Burnell, chairman, Genesee County Medical Society Cancer Committee, was recently presented a meritorious service award of the American Cancer Society for his leadership in cancer control during the last five years.——Dr. Darrell A. Campbell, formerly of Charleston, W. Va., has accepted the position of chief of the surgical staff of the Wayne County General Hospital and Infirmary, Eloise.

Annual Cancer Day.—The second annual Cancer Day, sponsored by the Genesee County Medical Society, will be March 19. In a scientific program in the auditorium at Hurley Hospital, Flint, the following speakers will participate: Drs. Albert C. Furstenberg, dean, University of Michigan Medical School, Ann Arbor; George Papanicolaou, associate professor of anatomy, Cornell University Medical College, New York City; G. Gavin Miller, professor of surgery, McGill University Faculty of Medicine, Montreal, Canada; David Steel, radiologist, St. Joseph's Hospital, Cleveland; Cornelius P. Rhoads, medical director, Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York City. The evening program in the ballroom of the Durant Hotel is open to the public. Charles F. Kettering, Ph.D., Detroit, will be the speaker.

MINNESOTA

License Revoked.—On July 12, 1946 the Minnesota State Board of Medical Examiners revoked the license to practice medicine previously issued to Dr. Jerome Ettinger, Minneapolis, who had been convicted on theft charges.

Reorganize State Health Department.—The Minnesota Department of Health, hitherto operating under nine divisions, has been reorganized under five sections: departmental administration, preventable diseases, medical laboratories, environmental sanitation and special services. The chiefs of the five sections will also serve as an advisory council to Dr. Albert J. Chesley, Minneapolis, the executive health officer of the health department.

NEW JERSEY

Physician Sentenced.—According to the New York *Times*, Dr. Leopold Brandenburg, Union City, has been sentenced to four to five years in state prison and fined $1,500 in connection with his conviction on Nov. 28, 1946 on charges of abortion (The Journal, Feb. 9, 1946, p. 362).

Amputee Clinic.—A month long amputee clinic opened February 3 at Hasbrouck Heights Hospital under the direction of Dr. Henry H. Kessler, Newark, former director of the navy amputation hospital at Mare Island, Calif. More than 200 orthopedic surgeons, mostly from New York, New Jersey and neighboring states, as well as artificial limb manufacturers and persons who have undergone amputations will take part. Dr. Kessler hopes to bring the benefits of army and navy wartime research on amputation to the civilians in this country who have lost arms and legs. While there were 17,000 service men who suffered amputations during the war, the number of civilians who lost limbs during the same period is 120,000, Dr. Kessler said. His program includes five points: Patients should be shown by demonstration what their abilities will be with an artificial limb; there should be close cooperation between artificial limb design and the surgical types of amputations performed; medical supervision of the stump should be continued until the artificial limb is properly fitted; design of the artificial limb should be suited to the occupation the patient expects to perform as well as to his general build; the patient should be educated at the hospital in the use of the artificial limb and its capabilities.

NEW YORK

Personal.—Dr. Harry A. Steckel, director of Syracuse Psychopathic Hospital, retired February 1 after thirty-four years of service. He will also leave his position of professor of psychiatry, Syracuse University College of Medicine, to take up the position of neuropsychiatrist to the regional office of the Veterans Administration in Syracuse on a part time basis.

Cancer Clinic.—A cancer prevention and detection clinic for doctors and nurses has been opened at Queens General Hospital, Jamaica. It is held on the second Monday of each month from 6 to 9 p. m., examinations by appointment only. The clinic is sponsored by the Queens County Cancer Committee and is under the directorship of Dr. Leonard B. Goldman, Elmhurst.

Public Health Nurses' Examination.—A statewide open competitive examination for public health nurses will be held some time in April to fill the present 148 positions available in thirty-three counties. Entrance salaries range up to $2,400. Candidates must be graduates of an approved school of nursing, have completed an approved one year program of instruction in public health nursing or must have the equivalent of both. Persons interested are urged to write the State Department of Civil Service not later than March 21 requesting application forms and a detailed announcement.

Plans to Stimulate Student Nurse Enrolment.—The New York State Nurses Association, district 1, has launched plans to stimulate enrolment of student nurses in all hospital schools for professional nurses in New York. Tentative recruitment plans include a proposal to issue a pamphlet or brochure to all women students in the senior classes of high schools in western New York, listing professional schools of nursing and describing admission requirements and curriculums offered. Greater emphasis will be placed henceforth on the desirability of a professional nursing education for well qualified students. In addition, a speakers' bureau will be established.

Examinations for Mental Hygiene Positions.—The state of New York aims to expand its treatment, training and research services in mental hygiene, child guidance and delinquency prevention programs and has opened opportunities for professional workers in these fields who are residents of New York. Examinations will be held March 22. A senior and an assistant research psychiatrist are needed for special projects of laboratory and clinical character in the department of mental hygiene, whose centers are located in Syracuse, New York City and Orangeburg. Research psychiatrists of the senior group also carry on some teaching activities at either Syracuse University College of Medicine or the College of Physicians and Surgeons at Columbia. The range of salary in the senior grade is from $4,560 to $5,700. For the assistant grade it is from $3,681 to $4,560. Senior psychologists at $3,681 to $4,560 a year are being sought for state and county departments and institutions. Junior psychologists at $2,268 to $2,806 are needed for institutions and for the departments of mental hygiene, division of prevention, Albany. Further information may be obtained by writing to the State Department of Civil Service, Albany, N. Y., stating positions in which one is interested: senior research psychiatrist, No. 4359; assistant research psychiatrist, No. 4332; senior psychologist, No. 4358; junior psychologist, No. 4352.

New York City

Narcotic Violation.—Dr. I. Hugo Francese, 635 East 211th Street, Bronx, N. Y., was convicted in the United States District Court at New York City of violation of section 2554(a) of the Internal Revenue Code and was sentenced on January 13 to serve a term of eighteen months.

Personal.—Dr. Sigmund L. Friedman, assistant administrator of Beth Israel Hospital, Boston, has been appointed executive director of Sydenham Hospital, effective February 3. Dr. Friedman is a graduate of the college and medical school of New York University and served as resident in hospital administration at Montefiore Hospital for Chronic Diseases before going to Boston three years ago.——Dr. Franklin M. Foote, New York, has been named medical director of the National Society for the Prevention of Blindness. Dr. Foote formerly was chief of the division of local health administration, Connecticut State Department of Health, and is now assistant professor of public health in preventive medicine, Cornell University Medical College.——Dr. Louis F. Bishop Jr. was named one of the honorary police surgeons of New York City in December by Mayor O'Dwyer.

Soot Fall Averages 112 Tons per Square Mile.—Mayor William O'Dwyer early this month called on forty municipal agencies, civic organizations, medical societies and industrial groups in the metropolitan area to set up a "citizens' committee";

to help clear the atmosphere of the New York area. Soot fall figures for 1946 average 112 tons each square mile, compared to a prewar average of 55 tons. Figures for 1936, the first year and only prewar year such an investigation was made, show an average of 105.6 tons in industrial areas. Dr. Israel Weinstein, health commissioner, has a seven man squad of full time smoke inspectors in the field and expects to increase the force to thirty-five. Their work will be largely educational. Chief causes of soot fall are wrong fuel and improper firing.

OHIO

Dr. Jorpes of Stockholm to Lecture at Columbus.—The annual Alpha Omega Alpha lecture at the Ohio State University School of Medicine at Columbus will be delivered by Dr. Erik Jorpes of Stockholm, Sweden, in April. This will be one of a series of lectures which Dr. Jorpes will present while visiting this country.

Public Welfare Appointments.—Dr. Mark W. Garry, former director of the tuberculosis division of the Ohio Department of Health, has been appointed to the position of chief of tuberculosis and internal medicine of the division of mental hygiene. Dr. Garry is a graduate of Marquette University School of Medicine and has been with the Department of Health since 1945. Dr. Elizabeth Bryan, formerly of Children's Hospital, St. Louis, has been named medical director of crippled children's service, under the division of social administration.

PENNSYLVANIA

Personal.—Dr. J. Norman White, Scranton, recently resigned as chief of staff of the Moses Taylor Hospital after many years of service.——Joseph B. Cady, chief of the section of cardiology and thoracic medicine at the Robert Packard Hospital in Sayre, is the newly appointed medical director at the State Rheumatic Heart Clinic at Sayre.

Philadelphia

Forum on Biologic Warfare.—The potentialities and implication of bacteriologic warfare are the subject of discussion at a public forum to be sponsored by the Association of Philadelphia Scientists on Thursday, February 27. The meeting is an outgrowth of the study of the problem in international control of the implements of warfare undertaken by the council in accordance with a resolution approved by the membership of the association last November. Physicians and biologists who have assisted the council include Dr. Edward L. Bortz, Lankenau Hospital, and Drs. Stuart Mudd and Harry D. Bruner and Thomas F. Anderson, Ph.D., of the University of Pennsylvania. Dr. Oram Woolpert, director of Camp Detrich, Frederick, Md., the biologic warfare research center of the army, was invited to attend.

UTAH

Cited for Clinical Investigative Work.—The department of obstetrics and gynecology of the University of Utah School of Medicine, Salt Lake City, was recently awarded the annual prize for 1946 by the Central Association of Obstetricians and Gynecologists for the best clinical investigative work. The research described in the paper was the work of Drs. Emil G. Holmstrom and Charles E. McLennan on "Menorrhagia Associated with Irregular Shedding of the Endometrium."

WEST VIRGINIA

Child Health Director.—Dr. Isabel Morgan, Ann Arbor, Mich., who has been on the staff of the School of Public Health at the University of Michigan for the past two years, has been appointed director of the division of maternal and child health, state health department, effective February 1. Dr. Norman G. Angstadt, Charleston, has been acting director of the division since the resignation of Dr. Lenore Chipman, Williamstown, Ky., in 1944. Dr. Angstadt has resigned to accept appointment as director of the department of medical supervision of the school district of Reading, Pa.

Governor Appoints Hospital Advisory Council.—A state advisory council has been appointed by Governor Clarence W. Meadows to consult with the state health department in carrying out the purposes of the Hill-Burton hospital construction act. The bill itself provides that an advisory council of laymen and physicians be designated before an application for funds can be approved. The physicians on the advisory council appointed by the governor are Paul H. Revercomb, Charleston; Oscar B. Biern and Robert J. Wilkinson, Huntington; Marvin H. Porterfield, Martinsburg; Richard O. Rogers, Bluefield; William R. Laird, Montgomery, and Andrew E. Amick, Lewisburg.

GENERAL

College Health Conference.—The third National Conference on Health in Colleges, the first meeting of its kind in more than ten years, will be held in New York City May 7-10, sponsored by thirty-five leading organizations in health and education. It is called to meet new health problems arising during the postwar period.

Dr. Herwick Resigns.—Dr. Robert P. Herwick, medical director of the U. S. Food and Drug Administration since 1938, has resigned and accepted an appointment as medical director of the Whitehall Pharmacal Company, a division of American Home Products Corporation. He will supervise product control and research. He has also resigned as a member of the Council on Pharmacy and Chemistry of the American Medical Association.

Yellow Fever and Plague.—*Public Health Reports* lists the following number of cases of yellow fever reported through consular agents, international health organizations, medical officers in public health services and other sources for November 1946: French Equatorial Africa 3 (including 2 suspected cases) and the Ivory Coast in Africa 1 case. The cases of plague reported for the same period include, among others, India 2,309, Burma 206, Madagascar 25, Siam 11 and Buenos Aires, Argentina, 8. These numbers should not be considered as complete or final as regards either the list of countries or the number of cases.

Southwest Allergy Forum.—The Southwest Allergy Forum will meet March 31 and April 1 in the Washington-Youree Hotel, Shreveport, La. Dr. George L. Waldbott, Detroit, will open the session at 9 o'clock Monday, speaking on "Some Faults in Allergists' Routine." Other speakers include Drs. Bernhard Steinberg, Toledo, Ohio; Boen Swinny, San Antonio, Texas; Robert E. Stone, Birmingham, Ala.; James H. Black, Dallas, Texas; Mr. Oren C. Durham, Chicago; Dr. Tinsley R. Harrison, Dallas, Texas; Dr. Francis M. Rackemann, Boston, and Dr. Jerome Glaser, Rochester, N. Y. Round table discussions will be held on dermatologic allergy, treatment of hay fever and nutritional problems in allergy.

Awards to Medical Students.—Bent G. Boving, a junior student at Jefferson Medical College, Philadelphia, has been awarded the first prize, $500, in the 1946 competition sponsored by the Schering Corporation, Bloomfield, N. J., for his essay on "The Role of Hormones in Sterility." The second prize, $300, was awarded to William O. Maddock, a student of the University of Oregon Medical School, and the third prize to Stonewall B. Stickney, Tulane University of Louisiana School of Medicine, New Orleans, and Lionel M. Mapp, McGill University Faculty of Medicine, Toronto, each of whom received $200. These awards are offered annually to undergraduate students in the United States and Canada for the purpose of stimulating interest in endocrinology.

Pan American Congress on Tuberculosis.—The seventh Pan American Congress on Tuberculosis will be held in Lima, Peru, March 17-22. The following fellows of the American College of Chest Physicians will be delegates: Drs. Chevalier L. Jackson, Philadelphia, chairman, Council on Pan American Affairs; Jay A. Myers, Minneapolis, editor, *Diseases of the Chest;* Richard H. Overholt, Brookline, Mass., first vice president; J. Winthrop Peabody, Washington, D. C., chairman, Council on Postgraduate Medical Education, and Mr. Murray Kornfeld, Chicago, executive secretary. The college maintains active chapters in a number of the South American countries and it is expected that a large delegation of physicians from those countries will attend its annual meeting at the Ambassador Hotel, Atlantic City, June 5-8.

National Heart Week.—Beginning with National Heart Week February 9-15 and continuing through the year, the American Heart Association will carry out a program of research, service and education in an effort to concentrate on educating the public with regard to problems of heart disease. The association's program calls for emphasis on educational work with schools, parent-teacher associations and other groups concerned with children because of the importance of rheumatic fever and heart disease among children. The war forcibly dramatized the need for a national program designed to retard the increase in cases of heart disease. Dr. Thomas Parran, surgeon general, U. S. Public Health Service, has pointed to the rise of heart disease from fifth place as a cause of disease in 1900 to first place today. The modern physician, he says, knows that heart disease will kill about twice as many people this year as will cancer and about seven times as many as tuberculosis. One out of every 20 persons suffers from diseases of the heart and blood vessels.

International Congress on Legal Medicine.—The second International Congress of the International Academy of Legal and Social Medicine will be held in Belgium (Brussels and Liége) June 25-28. The activities will be divided into five sections: legal medicine in its applications to crime, social medicine, industrial medicine, medicolegal and social psychiatry and scientific police. The official languages will be English and French. The academy will take advantage of this opportunity to promote a renewal of international cooperation in these fields of science. This cooperation will be established on a new basis, which will take largely into account the circumstances borne of the late war. Persons who wish to present reports or read papers should notify without delay either the president of the congress, Prof. Dr. Maurice De Laet, Faculté de Médicine, 7 Rue de la Gendarmerie, Brussels, or one of the general secretaries, Prof. Dr. P. Moureau, 47 Rue Villette, Liége, and Prof. Dr. Frederic Thomas, 23 Kluyskensstraat, Ghent.

Dr. Esmond Long Appointed Director of Research.—The National Tuberculosis Association has appointed Dr. Esmond R. Long director of its newly created Division of Research. While the association has had a committee on medical research for years, its research activities are being expanded by bringing into the division the work on medical research, activities in the field of social research, certain parts of the statistical program and its expanding work on historical research. Each of these departments will be covered by a voluntary committee of the members of the association or a special group within the central office. The committee on medical research is being continued within the division under the chairmanship of Dr. H. Stuart Willis of the Maybury Sanatorium, Northville, Mich., and is cooperating intimately in such present day research as chemotherapy of tuberculosis, BCG vaccination and antibiotics. While much of the administrative work and the financial details of the new division will be handled in New York City, Dr. Long will continue his duties as director of Henry Phipps Institute for the study, treatment and prevention of tuberculosis of the University of Pennsylvania, which has taken part in the research work of the National Tuberculosis Association for many years. During the war Dr. Long was chief consultant on tuberculosis in the Surgeon General's Office and for a time also served as acting director of the tuberculosis service of the Veterans Administration. He continues to serve the Veterans Administration and the army and also the U. S. Public Health Service as consultant on tuberculosis.

The Toll of Accidents.—The National Safety Council reports that 100,000 persons died in accidents in 1946 and 10,400,000 were injured. The estimated total economic loss from accidents was $5,600,000. This toll is 4 per cent above that of 1945; however, deaths of children from accidents in the 5 to 14 age group decreased 8 per cent. Deaths from accidents in 1946 as compared to 1945 were as follows:

	1946	1945	Change
All accidents	100,000	95,918	+ 4%
Motor vehicle	33,500	28,076	+19%
Home (civilian)	34,000	33,500	+ 1%
Occupational (civilian)	16,500	16,500	0%
Public (civilian not motor vehicle)	17,000	16,000	+ 6%

The 1946 all accident death rate was 71.4 per hundred thousand of population, the cause of death being: falls 27,800, burns 10,200, a 3 per cent increase over 1945, drownings 7,300, an increase of 2 per cent, firearms 3,100, an increase of 24 per cent, and catastrophes in which the toll was at least 5 lives 1,300. The greatest number of deaths, 34,000, occurred in the home. Disabling injuries in home accidents numbered 5,100,000, with a wage loss, medical expense and overhead costs of insurance totaling about $600,000,000. The traffic death toll of 33,500 was 19 per cent greater than in 1945 but below the all time high of 39,969 in 1941. In addition, 1946 traffic caused about 1,150,000 nonfatal injuries. All costs, including medical expenses, overhead costs of insurance and motor vehicle property damage was $1,650,000,000. Deaths from occupational accidents in 1946 totaled 16,500, about the same as in 1945. Disabling injuries from work accidents numbered about 2,050,000, with an economic loss totaling $2,350,000,000. The 1946 death total for public (not motor vehicle) accidents was approximately 17,000, an increase of 6 per cent from 1945. Nonfatal disabling injuries numbered about 2,100,000. Wage loss, medical expense and overhead costs of insurance totaled about $400,000,000. Fatal airplane accidents in domestic operation of scheduled air transports during 1946 numbered 12, with a death toll of 107, including 75 passengers and 32 crew members. This is a decrease of 43 per cent from the 1945 rate per hundred million passenger miles. Railroad accidents for the first eleven months of 1946 took a toll of 3,928 persons, a 7 per cent decrease from 1945. Resulting injuries dropped 15 per cent to a total of 49,049.

LATIN AMERICA

Allergy Clinics in South America.—Dr. Fred W. Wittich, Minneapolis, chairman Executive Committee International Association of Allergists, has just returned from holding conferences with allergy societies and allergy departments of the medical schools of South American countries and Cuba. The following countries have well organized allergy units in all the medical school polyclinics: Colombia at Bogota; Peru at Lima; Chile at Santiago; Argentina at Buenos Aires, Cordoba, La Plata and Rosario; Uruguay at Montevideo, and Brazil at Rio de Janeiro and São Paulo. In Havana there are allergy clinics at the Hospital de Maternidad Obrera and at the Asociacion Canaria Hospital of Havana. The Argentine government has established a National Institute of Allergic Diseases, and allergy diagnostic clinics are being established in rural and large centers. All the allergy societies of the countries mentioned are members of the International Association of Allergists. Spanish literature on allergy is accumulating fast. A close integration of the various departments exists in teaching allergy. A number of the allergists have spent one to two years of study in the United States at leading allergy clinics. In general, an excellent spirit of cooperation was noted among the Latin American allergists.

FOREIGN

Influenza in Sweden.—The New York *Times* reports that one fourth of the population of Sweden has been stricken with influenza. To help combat the epidemic 2,000 vials of influenza virus vaccine were shipped from La Guardia field, New York, February 6.

Foundation Terminates Grants to China College.—The Rockefeller Foundation has made its terminal contribution of $10,000,000 to the China Medical Board, Inc., for the support of Peiping Union Medical College, making a total of $44,652,490 it has appropriated to the college since 1915. The institution has graduated 350 doctors and 178 nurses, and more than 3,000 men and women have taken postgraduate studies. During the war thirteen of the seventeen nursing schools in free China were headed by graduates of the college's school of nursing. During the war years the college was in the hands of the Japanese and about 50 per cent of its medical equipment was removed. Dr. Harold H. Loucks, representative of the China Medical Board said "The commission was prompted by the looting of the medical school's equipment and the government postwar medical problem in China." Since early in 1946 the buildings have been used as executive headquarters of the peace commission endeavoring to arrange peace between the Chinese National Government and the Communists in that area. No date has been set for the resumption of the regular work at the college and hospital.

Marriages

Arthur Lawrence Bellott Jr., Memphis, Tenn., to Miss Grace Nadene Curde of Watauga in Elizabethton September 21.

Gregory Edward Flynn, Sea Girt, N. J., to Miss Margaret Lorraine Nugent of Lawrence, Mass., in Seattle October 19.

Henry Toole Clark Jr., Rochester, N. Y., to Miss Blanche Evelyn Burrus of Canton, N. C., October 1.

Charles Eugene Yeargin, Greenville, S. C., to Miss Jean Shaw of Boston in Laurens September 6.

Edward Riley Cannon, Andover, N. Y., to Miss Katherine Johanna Garvin of Oneida September 16.

Ralph Stuart Clayton, Ripley, Miss., to Miss Mary Bess McFatridge of Coldwater August 27.

John J. Hartford, Salina, Kan., to Miss Katharine Ann Kufahl of Emporia October 19.

Linus Worth Hewit to Miss Thelma Jane Hughey, both of Tampa, Fla., September 28.

Wyeth Hamlin, Palmyra, Mo., to Miss Mary Ann Gardner of Clinton, Ill., September 19.

Richard Hugh Wood, Atlanta, Ga., to Miss Nell Lawson Melton in Macon August 24.

Harry Fishbein, New Orleans, to Miss Lela Marion Hewes of Biloxi, Miss., October 3.

Swift C. Black, Springfield, S. C., to Dr. Susanne Geist of St. Paul August 19.

Morton H. Edelman to Miss Hilda Wyner, both of New York September 12.

Deaths

George Albert Ingrish ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1931; professor of urology at the Cook County Graduate School; specialist certified by the American Board of Urology; member of the American Urological Association; served during World War II; attending urologist, Illinois Central Railroad; affiliated with the Cook County Hospital, Evangelical Deaconess Hospital, Englewood Hospital, Holy Cross Hospital, Roseland Hospital, Woodlawn Hospital and the Little Company of Mary Hospital, where he died Dec. 17, 1946, aged 40, of acute leukemia.

Arthur Franklin Barnett ⊕ Eugene, Ore.; Rush Medical College, Chicago, 1904; served as president of the Lane County Medical Society and the Central Willamette Medical Society; specialist certified by the American Board of Radiology; member of the American College of Radiology; on the staff of the Sacred Heart Hospital, where he died Nov. 29, 1946, aged 66, of gastrointestinal hemorrhage.

Edward Francis Besser, Newton, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; member of the American Medical Association; died Nov. 21, 1946, aged 71, of coronary occlusion.

Andrew Baxter Byerly, Cooleemee, N. C.; University College of Medicine, Richmond, 1896; member of the American Medical Association; affiliated with the Rowan General Hospital in Salisbury; died Nov. 4, 1946, aged 77, of coronary occlusion.

Herbert A. Chipman, Stoughton, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1890; for many years health officer; served as alderman; died in the Stoughton Hospital Dec. 13, 1946, aged 81, of uremia.

Frederick Charles Horsford, West Point Pleasant, N. J.; Columbia University College of Physicians and Surgeons, New York, 1900; also a graduate in pharmacy; served during World War I; affiliated with the Presbyterian, City and St. James hospitals, all in Newark; formerly on the staff of the State Hospital, Greystone Park; died Dec. 8, 1946, aged 75, of coronary occlusion.

Douglas Jennings, Bennettsville, S. C.; Medical College of the State of South Carolina, Charleston, 1919; member of the American Medical Association and the Southeastern Surgical Congress; past president of the South Carolina Medical Association and the Tri-State Medical Association of the Carolinas and Virginia; on the staff of the Marlboro County General Hospital; trustee of his alma mater and the city schools; died in the Roper Hospital, Charleston, Dec. 1, 1946, aged 52, of coronary thrombosis and hypertension.

Edward Stanton Jones, Girard, Pa.; Ohio Medical University, Columbus, 1902; served during World War I and on the staffs of various Veterans Administration hospitals; died in Hamot Hospital, Erie, Dec. 8, 1946, aged 74, of arteriosclerotic heart disease.

William Joseph McKillip ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1916; specialist certified by the American Board of Urology; for many years urologist for the city health department; served during World War I; on the staffs of the Misericordia and Evangelical Deaconess hospitals; consulting urologist, Veterans Administration Hospital in Wood; died Dec. 9, 1946, aged 59, of coronary occlusion.

Herbert Albert Maillet, Butte, Mont.; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1903; at one time official examiner for the Montana State Athletic Commission; on the staff of St. James Hospital; died in Rochester, Minn., Dec. 1, 1946, aged 69, of carcinoma of the bladder.

Edwin Alonzo Mason, Troy, N. Y.; Albany (N. Y.) Medical College, 1902; on the staffs of the Leonard and Samaritan hospitals; died Dec. 12, 1946, aged 70, of cerebral hemorrhage.

Helen B. Molnar-Sasko ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; died Nov. 21, 1946, aged 71, of arteriosclerotic heart disease.

Charles A. Moulton, Hartland, Maine; Medical School of Maine, Portland, 1884; member of the American Medical Association; past president and honorary member of the Maine Medical Association; trustee of the Scott-Webb Memorial Hospital; died Dec. 7, 1946, aged 86, of coronary occlusion.

Edward William Mueller ⊕ Chicago; Rush Medical College, Chicago, 1902; fellow of the American College of Surgeons; on the staff of the Ravenswood Hospital; died Dec. 8, 1946, aged 66, of coronary occlusion.

Francis Jeremiah Vincent O'Brien, Rochester, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1899; served during World War I; on the staff of St. Mary's Hospital; died Dec. 6, 1946, aged 74, of cerebral hemorrhage.

George Stewart Ogden, Brooklyn; Hahnemann Medical College and Hospital of Philadelphia, 1898; member of the American Medical Association; on the staff of the Prospect Heights Hospital; died Dec. 10, 1946, aged 72, of carcinoma of the bladder.

I. Davis Ozmun, Miami, Fla.; Syracuse University College of Medicine, 1888; died in the Sun-Ray Health Resort Dec. 9, 1946, aged 90, of shock due to fractured femur received in a fall.

Eugene Constantine Piette, Oak Park, Ill.; University of Kharkov Faculty of Medicine, Russia, 1917; specialist certified by the American Board of Pathology, Inc.; served as associate professor of pathology on the faculty of the University of Illinois College of Medicine in Chicago; formerly on the faculty of his alma mater; served in the Russian army during World War I; author of several books; affiliated with the West Suburban Hospital, where he died Dec. 4, 1946, aged 54, of cerebral hemorrhage.

James Alonzo Poling, Freeport, Ill.; Northwestern University Medical School, Chicago, 1893; member of the American Medical Association; formerly city health commissioner and district health officer; served on the staff of St. Francis Hospital; died in a hospital at Moline recently, aged 79, of arteriosclerotic heart disease.

Elmer S. Protzman, Kenton, Ohio; Medical College of Ohio, Cincinnati, 1895; member of the American Medical Association; served during World War I; died in the San Antonio Hospital Dec. 4, 1946, aged 74, of arteriosclerosis.

Samuel Arthur Purves ⊕ Des Plaines, Ill.; University of Illinois College of Medicine, Chicago, 1934; interned at the Augustana Hospital in Chicago; on the staff of St. Francis Hospital in Evanston; member of the board of health in Des Plaines; died Dec. 11, 1946, aged 37, of injuries received when his automobile collided with a bus.

Emil Arthur Rach ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; formerly on the faculty of the Loyola University School of Medicine; an obstetric consultant for the city health department; head of the obstetric department at St. Bernard's Hospital, where he was past president of the hospital staff; died in St. George Hospital Dec. 7, 1946, aged 67, of coronary thrombosis.

Claude E. Ragsdale, Trafalgar, Ind.; Medical College of Indiana, Indianapolis, 1894; died in Indianapolis Sept. 14, 1946, aged 77.

Warren Henry Ristine, Crawfordsville, Ind.; Bellevue Hospital Medical College, New York, 1877; member of the American Medical Association; for many years president of the school board; died in Lakeland, Fla., Dec. 5, 1946, aged 96, of senility.

William Wellington Ryerson ⊕ Port Huron, Mich.; Detroit College of Medicine, 1911; formerly associated with U. S. Public Health Service; on the staff of the Port Huron Hospital; died Dec. 6, 1946, aged 58.

Elmer Alexander Scherrer, Denver; Washington University School of Medicine, St. Louis, 1897; member of the American Medical Association; veteran of the Spanish-American War; for many years on the staff of the Mercy Hospital; died Oct. 26, 1946, aged 71, of coronary thrombosis.

Samuel Harold Sedwitz ⊕ Youngstown, Ohio; University and Bellevue Hospital Medical College, New York, 1914; fellow of the American College of Surgeons; on the associate staff of the Youngstown Hospital; died in the North Side Unit of the Youngstown Hospital Dec. 6, 1946, aged 54, of cirrhosis of the liver.

John J. Stitt, Risingsun, Ohio; Ohio Medical University, Columbus, 1896; member of the American Medical Association; died recently, aged 77, of arteriosclerosis.

George Homer Zimmerman, Caldwell, Ohio; Ohio State University College of Medicine, Columbus, 1917; secretary-treasurer and past president of the Noble County Medical Society; on the staffs of the Bethesda Hospital in Zanesville and the Memorial Hospital in Marietta; died Oct. 7, 1946, aged 57, of coronary thrombosis.

Foreign Letters

LONDON LETTER

(From Our Regular Correspondent)

Jan. 27, 1947.

A Blood Group Reference Laboratory

The great increase in the practice of blood transfusion in civilian practice which has developed out of its extensive use in the war has been reported in previous letters to The Journal. The blood transfusion service established for the treatment of civilians who were injured in the attack on this country from the air has been maintained in peace by the government. The Galton Laboratory Serum Unit of the Medical Research Council was established at Cambridge and was closed last May. The director, Dr. R. R. Race, then took charge of a new blood group research unit of the council at the Lister Institute, London. His assistant at Cambridge, Dr. A. E. Mourant, has been appointed director of the new blood group reference laboratory of the Ministry of Health, which will provide grouping serum and investigate clinical blood group problems. This laboratory is also housed at the Lister Institute, and its juxtaposition to the research unit will ensure a close association between theory and practice. Hospitals and doctors in need of grouping serum must in the first instance apply to their local regional transfusion service, through which it will be issued.

Cancer Research

In its twenty-third annual report, for 1946, the British Empire Cancer Campaign announced an active program for the present year. The scientific advisory committee will be enlarged by the inclusion of separate biochemical, biologic and physical subcommittees, each consisting of experts in their own branches but subject to coordination by the parent committee. Much attention will be given to the relation of viruses to cancer; the grand council has been asked to provide $100,000 for the purpose. The government research committee on the medical and biologic applications of nuclear physics will include what the campaign would otherwise have undertaken on the effects of radiations of various wavelengths on vascular endothelium and other components. A central consultant panel in morbid histology, available throughout the country, has been formed by the campaign to assist, in conjunction with the Pathological Society and the national radium commission, in the diagnosis of obscure pathologic material. Other innovations are a scholarships and fellowships committee and a Hospital Physicists Association. The former will enable the campaign to recruit new workers, and the latter will serve as a kind of library of physical data too extensive for full publication in journals.

Finally, the campaign announces a new journal the *British Journal of Cancer,* which will be its official organ. The first number will appear in the spring. The annual subscription will be $8.40, and the publishers will be Messrs H. K. Lewis & Co. Ltd., 136 Gower Street, London, W. C. 1.

Exhibition Showing the Conquest of Disablement

The Ministries of Labor, of National Service and of Health have opened an interesting exhibition in London entitled "And So to Work," which is another example of the great attention being paid to rehabilitation. The disabilities concerned may be due to war service, physical weakness or illness. The exhibition shows what can be done to rehabilitate the victim. There are 75 operators taking part in the exhibition, of whom 44 are ex-service men, including some wounded in the war of 1914-1918. The remainder are civilians disabled by accident or disease.

The disabilities of the operators include loss of both arms and loss of hearing, sight or speech. Of blind operators three civilian shorthand typists and two ex-service telephonists are employed by the Ministry of Labor. At the exhibition may be seen draftsmen, dressmakers, boot and shoe makers, typewriter mechanics, saddlers, diamond polishers, tailors, printers, watch and clock repairers, basket makers, spectacle frame makers and artificial leg makers, all following their crafts with uncanny efficiency. An automobile firm (Vauxhall Motors Ltd.) shows as a separate exhibit its own scheme for bringing back to work the disabled, whether from war wounds or from accidents in civil life.

Retirement of a Great Venereologist

Col. L. W. Harrison, adviser on venereal diseases to the Ministry of Health since 1919, has retired. He has been associated with the control of these diseases for nearly half a century and is the leading authority on the subject. In recognition of his work the American Social Hygiene Association awarded him the William Freeman Snow medal for 1946. This annual reward for distinguished service to humanity is a medical replica of the portrait plaque, which in 1937 was presented to Snow to mark his fortieth year of service in the field of public health and social hygiene. Appointed as pathologist to the Rochester Row Military Hospital, London, in 1909, Harrison did pioneer work in devising aids to the diagnosis of venereal diseases. He played a leading part in investigating the efficacy of arsphenamine. In 1915 he took charge of the Venereal Disease Military Hospital established at Le Havre in the first world war and the only one in France at the time. In the following year he took command of the Military Hospital, Rochester Row, and became adviser on venereal disease to the War Office. From 1919 onward he combined the work of adviser on venereal disease to the Ministry of Health, with directorship of the venereal diseases department, St. Thomas's Hospital.

During his first twenty years at the Ministry of Health considerable progress was made in the control of venereal disease. Clinical attendances indicate that early syphilis decreased by about two thirds between 1920 and 1939. It is estimated that the incidence of venereal disease in British troops stationed in this country in the recent war was only two fifths of the rate in the first world war. But in the recent war there was a steep increase, favored by war conditions, from 1940 onward. Thus the incidence of early syphilis increased from 4,986 in 1939 to 10,741 in 1945. Harrison's last years at the ministry were marked by an energetic campaign against venereal disease. Increased facilities were provided for diagnosis and treatment, and a regulation was made to control the spreader of venereal disease. Harrison is the author of "The Diagnosis and Treatment of Venereal Diseases in General Practice," which has reached a fourth edition, and other books.

SPAIN

Madrid, Dec. 24, 1946.

Medical Congresses

DERMATOLOGY

On May 16-18, 1946, the first Hispano-Portuguese Dermatology Congress was held in Valencia, combined with the fourth national meeting of Spanish dermatologists. These assemblies were attended by dermatologists from all parts of Spain, headed by Professors Peyri Rocamora (Barcelona), Gay Prieto (Madrid) and Vilanova (Valencia). The president of the congress was Professor Sainz de Aja. The Portuguese representatives were led by Professor Sa Penella, of Lisbon.

The first report, on leprosy, was divided into three parts: on general pathology of the leprous infection, by Dr. Gonzalez Medina, anatomoclinical forms and classifications of leprosy, by Dr. Contreras Dueñas, and the epidemiologic map of leprosy, by Dr. Berjillos del Rio.

The second report, on psoriasis, was dealt with in four papers: the etiology, pathogeny and internal treatment of psoriasis; by

Dr. Mercadal Peyri, clinical forms, evolution and external treatment of psoriasis, by Dr. Senra Calvo, the pathology of psoriasis, by Dr. Esteller Luengo, and the differential diagnosis of psoriasis, by Dr. Lopez Martinez.

The third report, on penicillin in dermovenereology, was read by Dr. Alvarez Lowell.

Important communications were also read on all these subjects and on eczema, syphilis, gonorrhea, Nicolas-Favre's disease, leishmaniasis, cutaneous tuberculosis, skin tumors, allergic dermatoses, erythematodes acutum, Besnier-Boeck-Schaumann's syndrome, metabolic dermatoses, sclerodermia, pigmentary urticaria and other matters, some of them historical. The members of the congress visited the Lepers' Hospital, for 350 patients, at Fontilles, the best institution of its kind in Spain. Finally, it was agreed to hold the next meeting in Lisbon.

UROLOGY

From June 17 to June 22 the fifth Hispano-Portuguese Urology Congress met in the Royal Academy of Medicine in Madrid under the presidency of Professor Pedro Cifuentes of the Princesa Hospital. Professor Gil Vernet of Barcelona read a paper on carcinoma of the prostate and its treatment, the Portuguese physicians Reynaldo Dos Santos, Bastos, Carneiro, Moraes and Dos Santos Jr. intervening in the debate besides the Spaniards Oreja, Paez, Cifuentes, Picatoste and Puigvert. There were discussions on renal anomalies, sympathetic surgery, penicillin in urology and parathyroid and renal lithiasis. Those taking part were Drs. Ipiens, Moraes, Maza, Moysés, Paez, Serrallach, Da Silva, de la Peña, Laires, Levy, Piñeiro, Ravara, Dos Santos and Dos Santos Jr., Picatoste, Ribeiro, Osuna, Martinez, Martinho, Molina and Alcalá. Surgical demonstrations were presented by Dr. Gil Vernet in the General Hospital, by Dr. Dos Santos Jr., in the Red Cross Hospital and Dr. A. de la Peña in the Ruber Nursing Home. It was agreed to hold the next congress in 1948 in Portugal, with Dr. Cid Dos Santos, for Portugal, expounding the subject of sympathetic surgery in urology and, for Spain, Dr. L. Cifuentes Delatte dealing with nonspecific cystitis. Both these doctors have been doing important work on their respective subjects in the last few years. It is worth pointing out that for this congress the organizing committee was appointed by the Public Health Department of the Ministry of the Interior without any free election of its members, since the appointments thus made for the last congress, held in Cadiz, were canceled by the actual state authorities.

OPHTHALMOLOGY

Finally, between September 9 and 14, we had the twenty-fourth assembly of the Hispano-American Ophthalmology Society at La Toja Spa in Galicia under the presidency of the Catalan professor Dr. H. Arruga, who ultimately withdrew in favor of Dr. E. Diaz Caneja, the director of the Valdecilla Health Center in Santander. There were debates on a long communication on the etiopathogeny of Glaucoma drawn up by Dr. Moreu, assistant professor of ophthalmology in the Valencia Faculty of Medicine; and Drs. E. Diaz Caneja, Soria, Leoz, Marin Amat, Costi and others participated in the discussions. Dr. Echeverri of Santiago de Compostela read a paper on the classic concepts and new ideas concerning the embryology of the eyeball. Many papers were read, special mention being due to Professor B. Carreras Duran's on technical contributions to dacryocystorhinectomy and ocular manifestations of congenital porphyria, Dr. Martin Amat's on the importance of deep suture for the success of dacryocystorhinectomy, Drs. Costi and Larru's on the treatment of ocular neoplasia by Chaoul's x-ray technic, Dr. H. Arruga's on simplified measurable tenotomy. Dr. Leoz Ortin's on postoperative endogenous ocular infections and the cataract operation in high myopia states and Dr. Costi's on peripupillary ectasia of the sclerotic. At the next congress, to be held in 1950, the subject for debate will be introduced by Dr. Mata, who will speak on retrobulbar neuritis.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Jan. 15, 1947.

Cardiac Lesions in Pulmonary Tuberculosis

In a recent paper Dr. Jairo Ramos of the São Luis Gonzaga Hospital of Jassanan, São Paulo, reports a study of 107 cases of cardiac lesions in patients with chronic pulmonary tuberculosis. Among these cases a well characterized cardiac failure was the apparent cause of death, although 31 more cases presented typical hepatic changes as a consequence of right ventricular failure without any other sign of circulatory disturbance. Of the 107 cases, 47 were selected for special study, since they presented dilatation and hypertrophy of the right ventricle, or at least of its arterial orifice. In 20 cases the heart was perfectly normal. It is interesting that the pulmonary lesions were almost equally prevalent in the cases with or without cardiac lesions. Thus the author believes that the type and the extent of the chronic pulmonary lesions do not seem to be the main causative factors of the cardiac changes disclosed by postmortem examination.

In a study of associated lesions in cases with or without cardiac changes, the author concluded that pleural lesions, such as adhesions and partial or total fusion, do not seem to be the main causes of cardiac changes. Pulmonary emphysema seems to be of little import as a cause of disturbance of the right ventricle. Very important are chronic empyema and extensive areas of pulmonary atelectasis, and those anatomic changes did occur more frequently in patients with cardiac lesions, particularly in cases in which dilatation and hypertrophy of the right ventricle were present.

Carcinoma of the Pancreas

Drs. A. Penna de Azevedo and Rita A. Cardoso of the Oswaldo Cruz Institute, Rio de Janeiro, have published a review of 6,823 records of postmortem examinations performed at the Division of Pathology from 1919 to 1944, by Drs. Magarinos Torres, Eudoro Villela, Burle de Figueiredo and Eitel M. Duarte. The report disclosed the existence of 686 cases of cancer of different organs, among which were 28 of primary carcinoma of the pancreas, giving a rate of 0.4 per cent of primary carcinoma of the pancreas in the total number of postmortem examinations and of 4.1 per cent in the series of cases of cancer. The tumor was localized in the head of the pancreas in 20 of the cases (71.4 per cent), in the tail in 1 case (3.5 per cent) and was diffuse in 5 cases (17.8 per cent). There was no record of location in 2 cases (7.1 per cent). The predominant histologic type was the adenocarcinoma, recognized in 21 of the cases (75 per cent), the rest being of acinous carcinoma. As a rule the cirrhotic type was observed, and in some of the cases the formation of mucin was conspicuous.

The incidence of metastases was 95 per cent (20 cases) in the 21 cases of adenocarcinoma, and 100 per cent (7 cases) in the cases of acinous carcinoma. The incidence rate of metastases in the different organs, in decreasing order, was liver and lymph nodes 70.3 per cent each, peritoneum 25.9 per cent, lungs 22.2 per cent, adrenals 18.5 per cent and the pleura, spleen and kidneys 7.4 per cent each. In only 1 of the cases metastasis was not present. The largest concentration of cases occurred in the age group 40-59 years, with 11 cases, or 39.3 per cent, of the total.

Death of Dr. Estellita Lins

Dr. A. Estellita Lins, a urologist and professor at the Faculdade de Ciencias Medicas of Rio de Janeiro, died at the age of 57. Dr. Lins, a member of the Brazilian College of Surgeons and of the National Academy of Medicine, had served in the medical corps of the Brazilian Expediti Force in Italy during the war.

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D D N J. and foods, F. N J The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment; (4) the composition, (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration]

Armstrong's Drops—F E Bucklin Company, Los Angeles Labeled in part 'Manufactured for Armstrong Drop Co, So Pasadena, Cal" Shipped May 17 and Oct 27, 1943 Misbranded because label failed to give accurate statement of quantity of contents, which were less than declared amount—[*D D N J, F D C 1238, June 1945*]

Beawun Vitamin B_1 Tablets—American Nutrition Company, Chicago Shipped May 18, 1943 Composition approximately 1 milligram of vitamin B_1 per tablet Misbranded because falsely represented in labeling to prevent and correct digestive disorders, neuritis, beri beri, delirium tremens and many other disorders—[*D D N J, F D C 1242, June 1945*] Also misbranded under provisions of the law applicable to foods, as reported in *F N J 7338*

Class' Vitamin, Mineral and Herb Formula.—Granville Class Laboratories, Dayton, Ohio Shipped Aug 19 and 25, 1943 Composition water, glycerin and alcohol, caffeine, phosphate compounds plant extractives and a trace of saccharin Misbranded because label falsely represented product to be valuable for its vitamin and mineral content, correcting poor health, nervousness and poor appetite through its vitamins, minerals and herbs, whereas it was not a significant source of these elements—[*D D N J, F D C 1243 June 1945*] Also misbranded under provisions of the law applicable to foods, as reported in *F N J 7342*

Colestin Natural Mineral Water.—Colestin Mineral Water Company, Medford, Ore Shipped Sept 8, 1943 Composition about 0 29 per cent of dissolved mineral matter reported Misbranded because label falsely represented product as effective for kidney, stomach and rheumatic troubles, biliousness and similar conditions—[*D D N J, F D C 1183 June 1945*]

Dextro-Quinine—Distributor not reported Shipped Aug 27, 1942 Composition plant extractive material, about one half of which had alkaloidal characteristics Misbranded because name falsely represented that product was quinine or a dextro rotatory isomer of quinine—[*D D N. J, F D C 1140, June 1945*]

Dr. Marshall's Scalp Medications—T Noonan & Sons Company, Boston Shipped May 28 and July 30, 1943 Treatment consisted of four products Scalp Cream No 1 was a mixture of sulfur, salicylic acid and tar oils in a base of petrolatum and lanolin Misbranded because label falsely represented product as efficacious in treating oily dandruff and psoriasis Scalp Cream No 3 contained sulfur, balsam of Peru and betanaphthol in a petrolatum and lanolin base Misbranded because falsely represented as efficacious in treating falling hair or bald spots Scalp Lotion A consisted essentially of betanaphthol, quinine, resorcinol and a saponifiable oil such as castor oil, with alcohol and water Falsely represented as a competent treatment for psoriasis or oily dandruff Scalp Lotion B was a mixture of betanaphthol, resorcinol, alcohol and water, perfumed with aromatic oils Misbranded because falsely represented as an efficacious treatment of oily hair, oily dandruff or psoriasis The two Lotions were further declared misbranded because labels did not declare amount or proportion of alcohol present—[*D D N J F D C 1239, June 1945*] In the same month another Notice of Judgment (*D D N J, F D C 1193*) was issued against Scalp Lotion A and Scalp Lotion B

Ell-606 Capsules—Ainsworth Specialty Company, Kansas City, Mo Shipped Jan 21, 1943 Composition in each capsule 0 154 grain of sodium cacodylate, 0 89 grain of methenamine, 0 386 grain of acetanilid, 0 49 grain of calcium phosphate, and 0 476 grain of sodium phosphate Adulterated because most ingredients were present in smaller amounts than declared on label Misbranded for the same reason, and because of label misrepresentations as to product's efficacy as a urinary antiseptic, blood cleanser and substitute tor, or supplement to, intravenous medication in venereal and other diseases—[*D D N J, F D C 1151, June 1945*]

Fairyfoot for Bunions—Fairyfoot Products Company, Chicago Shipped August 6 and Nov 17, 1943 *Composition* adhesive plaster pads containing benzocaine and a small amount of an iron compound Misbranded because of false label representation that product was effective in stopping the pain and reducing the size of a bunion—[*D D N J, F D C 1236, June 1945*]

Golden Key Antiseptic Medicated Cream—Windsor Chemical Laboratories, Philadelphia Shipped July 12, 1943 Composition not reported Misbranded because label failed to bear accurate statement of quantity of contents—[*D D N J, F D C 1240, June 1945*]

Hamby's Dawson Springs Water—*Dawson Springs Water Company, Inc*, Dawson Springs, Ky Shipped March 25, 1943 Composition essentially epsom salt, sodium sulfate, and water, with small amounts of sodium chloride and calcium sulfate Misbranded because, among other things, label did not warn that a laxative should not be used when abdominal pains nausea, vomiting or other symptoms of appendicitis are present, and because labeling falsely represented, among other things, that the product was essentially a natural spring water, an alterative and blood tonic, would heal mucous membranes and help many disorders, including diabetes, liver and kidney complaints, rheumatism, Bright's disease and gallstones—[*D D N J, F D C 1155, June 1945*]

Nelson's Antacid Powder—Cleveland Druggists Specialties Company (Great Lakes Laboratories), Cleveland Shipped May 25, 1942 Composition essentially compounds of sodium, calcium, magnesium and carbonate Adulterated because strength was not as represented, since product purported to contain bismuth salts, but did not Misbranded because label falsely declared "Bismuth Salts in the form of Carbonates Subnitrates" and falsely suggested that product would effectively treat gastric ulcers and other stomach disorders would convert all protein foods, such as meats and albumens, into soluble and readily absorbed peptones and all starchy foods into soluble dextrins and sugars, further misbranded because label did not accurately declare quantity of contents—[*D D N J F D C 1201, June 1945*]

Rainier Natural Soap—Rainier Natural Soap Company, South Boston, Mass Shipped June 30, 1943 Composition approximately 32 per cent of soap and 68 per cent of pumice or similar material Misbranded because falsely represented in labeling as a naturally occurring soap which would prevent or effectively treat eczema, rashes poison ivy, chafing, itching and burning skin conditions, blackheads, pimples and other disfiguring blotches— *D D N J, F D C 1195, June 1945*

Sano—Sano Medicine Company, Cleveland Shipped Feb 7, 1943 Composition a brown liquid with sediment, containing water, alcohol and plant extractives, including emodin bearing drugs and a trace of unidentified alkaloids Misbranded because label falsely represented that product was a diuretic and a tonic and would help to relieve rheumatism and to eliminate poisons, besides removing the cause Further misbranded because label did not adequately warn that the product was a laxative, should be taken only occasionally and as needed, and not used when abdominal pain, nausea, vomiting or other symptoms of appendicitis are present, or that frequent or continued use might lead to a dependence on laxatives—[*D D N J, F D C 1154, June 1945*]

Special Formula Tablets #2—Made by Arner Company, Inc, Buffalo, for Paul Case, Brockton Mass *Shipped July 3 and August 7, 1941.* Composition an extract of a laxative plant drug, such as cascara sagrada, with sodium bicarbonate and sodium citrate Misbranded because label did not bear common names of active ingredients or directions for use, and failed to warn that product should not be taken when abdominal pain, nausea, vomiting, or other symptoms of appendicitis are present—[*D D. N J, F D C 1157, June 1945*] Mention was also made of Paul Case's "Combination New Improved Method for 'Rheumatic' Pains" Paul Case's mail order "rheumatism cure' was exposed in *The Journal* Jan 12, 1924, page 145

Templeton's Raz-Mah Capsules—Templeton's, Inc, Buffalo Shipped Nov 10, 1943 Composition essentially aspirin 4 12 grains per capsule, caffeine 0 69 grain per capsule, and capsicum, charcoal and extracts of unnamed plant drugs Misbranded because labeling falsely represented product to be effective treatment or relief of symptoms of hay fever, bronchial irritations and coughs due to these or colds and also safe and helpful in asthma—[*D D N J, F D C 1234, June 1945*]

Vit-an-Min—S & R Laboratories, Inc, Chicago Shipped April 20, 1943 Composition a light brown, powdered material essentially containing vitamins A, D, B_1 and riboflavin, with calcium, phosphorus and iron Misbranded because label falsely represented that product would give the user health and beauty, insure normal functioning, correct abnormalities of brain and glands and cure or mitigate numerous other disorders—[*D D N J, F D C 1241, June 1945*] Also misbranded under provisions of the law applicable to foods, as reported in *F N. J. 7347*

Vita-Pure B-Complex Vitamins—Roisman Products Company, Oklahoma City, Okla Shipped March 30, 1943 Composition each tablet contained approximately the 333 U S P units of vitamin B_1 declared on label, but not more than 266 U S P units of vitamin B_1, whereas label declared 333 units Misbranded because label falsely represented that product would prevent or correct loss of appetite, mental depression, skin disorders, neuritis and some other things, that it would help keep one feeling fit, and that one tablet per day would afford the average minimum requirements of adults for B complex vitamins—[*D D N J, F D C. 1185, June 1945*] Also misbranded under provisions of the law applicable to foods, as reported in *F N J 7000*

Von's Tablets—George Von Neida, St Paul Shipped Dec 9, 1942, from Minneapolis to San Francisco Von Company, which relabeled part of consignment "Von's Pink Tablets" Composition in each tablet essentially 4 6 grains of bismuth subnitrate, 6 5 grains of magnesium oxide, and 5 4 grains of sodium bicarbonate Misbranded because accompanying booklets falsely represented that tablets, when used as directed, constituted *an adequate treatment* for gastritis and ulcers caused by gastric hyperacidity—[*D D N J, F D C 1233, June 1945*]

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Selective Service Act: Right of Discharged Army Medical Officer to Employment Held Prior to Entering Service.—This was an action under the reemployment provisions of the selective training and service act of 1940 to compel the reinstatement of the plaintiff as medical director of the defendant company. The case was heard in the United States district court, D., New Jersey.

In 1934 the plaintiff was employed as the chief company physician of the defendant corporation. At the time of his employment he occupied a desk in an office shared with the defendant's safety director, claims investigator and welfare director. He revised medical forms used by the company, was responsible for the designation of physicians' for preemployment examinations in various localities and made these examinations himself on applications for employment from persons residing in the vicinity of Asbury Park, N. J., for which he received fees in addition to his monthly salary. At the company office he did only executive work in the nature of reviewing files on compensation cases, noncompensable cases and preemployment medical records. His gross yearly income from this and other sources averaged $20,000 to $24,000. He testified that he had appeared daily (but according to his own time schedule) at his office in defendant's plant, his visits averaging a minimum of fifteen minutes and a maximum of one and one-half hours. During his employment he received no instructions, was never criticized and received only commendation for his work.

He entered the United States Army Oct. 6, 1942 and was discharged Nov. 28, 1945, his terminal leave expiring Feb. 2, 1946. Prior to his entry into the service he had discussed the question of leave of absence with company officials and had been advised by letter by the vice president as follows:

> So far as leave of absence is concerned you have it, of course, but, I am forced to add, for what it may be worth. Conditions are such that I cannot avoid the qualification inasmuch as your office is an appointive one and upon your return must be disposed of by those who then may be in charge. I need not reassure you that if Tom and I are still in the picture and needs require it, you will surely be back to your old post.

In 1944 the ownership of the defendant company changed, so the defendant changed insurance carriers to the one generally used in the new system of ownership. The department formerly supervised by the plaintiff is no longer operated by the defendant, since the present carrier employs counsel and medical examiners of its own choosing. When accidents occur now defendant makes a report to the carrier, and the carrier handles the matter from that point on. Review of records of preemployment examinations formerly made by the plaintiff is now done by the defendant's safety department and if any question arises it is referred to the examining physician. Review of noncompensable cases formerly made by the plaintiff is now handled by defendant's welfare department. The defendant's vice president testified that under the present arrangement there is neither place nor need for the medical activities previously performed by the plaintiff.

The plaintiff's claim was based on the following section of the selective training and service act:

> (B) if such position was in the employ of a private employer, such employer shall restore such person to such position or to a position of like seniority, status, and pay unless the employer's circumstances have so changed as to make it impossible or unreasonable to do so;

and the defendant contended among other things that its circumstances had so changed as to make it impossible or unreasonable to reengage the services of the plaintiff. The plaintiff argued that all the work that he formerly did is still performed, but through a change in company policy it is not done by defendant but by the carrier, and the plaintiff therefore contends that the defendant has, in effect, replaced his services by another.

In 1944, said the court, there was virtually a new ownership of this defendant. Its contract of insurance having expired, a new insurer, common to the new ownership's chain of companies, designed for the defendant a new pattern for insuring against losses. This new pattern did away not only with the plaintiff's position but the positions of the investigator and counsel as well. We are convinced, the court concluded, that this was carried out in good faith. Thus the defendant's circumstances were so changed as to make it unreasonable to compel the defendant to reemploy the plaintiff in a position the principal duties of which have completely disappeared. Accordingly the plaintiff's complaint was dismissed.—*Featherston v. Jersey Central Power & Light Co., 66 F. Supp. 882 (N. J., 1946).*

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Feb. 15, page 498.

BOARDS OF MEDICAL EXAMINERS

Arkansas: * *Medical. Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination.* Los Angeles, March 10-13. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Connecticut: * *Medical. Examination.* Hartford, March 11-12. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

Georgia: Atlanta and Augusta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Iowa: * *Examination.* Iowa City, March 17-19. Corresponding Sec., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

Kansas: *Examination.* Kansas City, March 25-26. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

Maine: Portland, March 11-12. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

Massachusetts: Boston, March 11-14. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston 33.

Montana: Helena, April 1-2. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

Nevada: *Examination.* Carson City, May 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: Concord, March 13. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico: * Santa Fe, April 7-8. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

North Carolina: *Endorsement.* Winston-Salem, April 30, June 24. *Examination.* Raleigh, June 23-26. Acting Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

Ohio: *Examination.* Columbus, June 17-20. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Pennsylvania: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

South Carolina: Columbia, June 23-25. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Texas: *Examination.* Galveston, Feb. 20-22. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: March 18, Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

District of Columbia: Washington, April 21-22. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: May 31. Final date for filing application is May 16. Sec., Dr. M. W. Emmel, University of Florida, Gainesville.

Iowa: Des Moines, April 8. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Oklahoma: Oklahoma City, March 17. Pres. Dr. Sam A. McKeel Ada.

Oregon: Portland, March 1. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps *to cover postage* (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Carcinoma of Adrenal Cortex with Adrenogenital Syndrome in Children: Complete Review of Literature and Report of Case with Recovery in Child 8 Months of Age. A. E. Goldstein and J. A. Askin.—p. 563.

Clinical Immunity in Poliomyelitis.—Bridge and his associates report 4 cases in which second attacks of poliomyelitis occurred and of 2 cases in which second attacks probably occurred. The proportion of these cases to the total epidemic of 1944 in the area around Buffalo is such as to cast doubt on the existence of significant acquired immunity. When reexposed to the disease some persons who have had poliomyelitis may have abortive poliomyelitis. From the literature it is also evident that one attack of poliomyelitis in experimental animals does not confer immunity against subsequent infection. It appears inadvisable to rely on acquired immunity to protect persons who may be in close contact with patients.

Familial Glycogen Disease.—Abramson and Kurtz report histories and pathologic examinations of 4 siblings of Jewish parentage who died during early infancy from glycogen storage disease of the von Gierke form. There was no evidence of direct transmission of the disease from the parents, nor could consanguinity of the parents be demonstrated. Four of 6 children in this family had the disease and in each of them the symptoms dated from birth. Abdominal distention, enlargement of the liver and respiratory distress were the principal symptoms. Contrary to the accepted opinion of a not unfavorable prognosis in glycogen disease, the 4 children died, 1 on the fourth day, 2 at 3 months and 1 at 4 months of age.

Pneumatocele During Pneumonia in Children.—According to Almklov and Hatoff x-ray examination frequently discloses the occurrence of a cavity in the lung during the course of pneumonia in children. The cavity has a sharply defined thin border and, in a large number of cases, an air-fluid level. These cavities are variously called pneumatoceles, emphysematous bullae or benign cavities, the authors preferring the term pneumatocele. They report 7 cases and stress that the demonstration of pneumatocele depends on the taking of serial roentgenograms of the chest during the course of the pneumonia. The mechanism consists of check valve action of bronchiole mucosa involved in the inflammatory process of pneumonia. The differential diagnosis is simplified by the benign, ephemeral character of the lesion. In the uncomplicated case no therapy is indicated.

Urethritis in Girls.—Roen and Stept direct attention to a little recognized entity, that of urethritis in girls, productive of a number of urinary symptoms generally attributed to pathologic changes of the upper urinary tract. Illustrative reports of cases are given to show the wide variation in symptoms that may be present, although the same pathologic features of chronic inflammatory urethral change characterize all the cases. Diagnosis is made by direct observation with the cystoscope and elimination of the upper urinary tract as a causative factor. Treatment consists in dilation of the urethra.

Complications Following Thiouracil.—Beierwaltes and Sturgis have collected 9 fatalities occurring during or following thiouracil administration. A review of 7 fatal cases of agranulocytosis associated with the administration of thiouracil shows that there are at least five important factors that contribute to the fatal outcome. These include failure to administer penicillin promptly, failure to discontinue the drug after the onset of symptoms, disregard of significant symptoms of impending agranulocytosis, inefficacy of various forms of therapy for agranulocytosis and failure to discontinue thiouracil when a severe leukopenia develops. The authors also discuss nonhematologic reactions which require cessation of thiouracil and reactions not usually requiring discontinuance of thiouracil. The most satisfactory method of preventing fatalities from agranulocytosis is to warn the patient who is taking thiouracil to discontinue the drug promptly on the appearance of fever with or without sore throat, skin rash or adenopathy. If a white blood cell count and estimation of the neutrophil percentage show a significant depression of the cells, penicillin should be administered until the blood count becomes normal again. Thiouracil therapy may then be resumed, but there is a risk of recurrence.

Combined Quinine and Plasmochin Treatment of Vivax Malaria.—According to Most and his associates a striking feature of vivax malaria of Pacific origin is its tendency to relapse after treatment with the malarial drugs currently in use. The authors are concerned with the effect on subsequent relapse following the simultaneous quinine and plasmochin treatment. Quinine sulfate 1 Gm. and plasmochin naphthoate 0.02 Gm. simultaneously at eight hour intervals for one day followed by quinine 0.65 Gm. and plasmochin naphthoate 0.02 Gm. simultaneously at eight hour intervals for the next thirteen days were administered to 72 white patients with acute attacks of vivax malaria of Pacific origin who were followed for at least 120 days after treatment. The clinical relapse rate and total failure rate during 120 days' observation was 4 and 11.1 per cent respectively. This is in sharp contrast to clinical relapse rates of 75 to 85 per cent and total failure of 85 to 90 per cent based on similar observations after treatment of more than 500 patients for acute attacks of vivax malaria of Pacific origin treated with quinine, quinacrine or other antimalarial drugs. No serious toxic manifestations were observed in patients who received combined quinine and plasmochin therapy.

Sulfadiazine in Bubonic Plague.—Huang and Chu studied the efficacy of sulfadiazine in bubonic plague in Fukien, China, in the summer of 1944. From the beginning of June to July 18, when their study began, 56 of 109 plague patients had died, giving a mortality rate of 51.4 per cent. Sixteen of the 25 cases treated by them were treated with sulfadiazine alone, 3 with sulfadiazine plus antiplague serum, 4 with sulfathiazole and serum at first but later with sulfadiazine and 2 with sulfathiazole alone. There were 5 fatalities—3 deaths among patients treated with sulfadiazine and 2 deaths among those treated with sulfadiazine plus serum. While admittedly a small series, the results are sufficiently striking to show the excellent therapeutic value of sulfadiazine in the treatment of bubonic plague.

Syphilis: Review of Recent Literature. F. W. Reynolds and J. E. Moore.—p. 592.

Canicola Fever.—Rosenbaum reports that a man aged 44 was hospitalized on the sixth day of illness, when he appeared jaundiced and acutely ill. On the thirteenth hospital day it was learned that the patient's dog had been suffering from a severe illness for the preceding two months. The patient was in the habit of fondling the dog. The serums of patient and dog were found to agglutinate Leptospira canicola to a dilution of 1:100,000 and Leptospira icterohemorrhagiae to 1:1,000. Leptospiras were never seen in the patient's blood. They were found repeatedly in the patient's urine.

Calcification of Mitral Annulus Fibrosus.—Rytand and Lipsitch present observations made during the lives of 10 elderly patients with calcification of the mitral annulus fibrosus. None had a history of rheumatic fever. Atherosclerosis was severe. Congestive heart failure occurred in 5 patients. Arterial hypertension was present in practically every case but was not severe. Four of the 5 patients with complete heart block have died, but only 1 of those without block has died. There was a moderate or a loud, rough murmur with ventricular systole in 7 of the patients. In the 4 ambulatory patients of the 5 with heart block there was a blowing apical murmur, related to auricular activity, during ventricular diastole; auricular sounds of uncertain nature were recorded for the fifth. This murmur did not occur in the patients with normal auriculoventricular conduction, but it has been noted in other elderly patients with heart block and without x-ray evidence of calcification. Calcification of the mitral annulus fibrosus may be suspected in elderly persons after the finding of heart block and an apical murmur associated with auricular activity during ventricular diastole.

Erysipelothrix Infection.—Ehrlich reports the history of a farmer who was hospitalized four days after he had slaughtered a sick hog. His erysipelothrix infection was distinguished clinically by the extremely rapid dissemination of the eruption, the severe pruritus and the development of huge bullae. These features and the microscopic observations, particularly the swelling of the collagen, the numerous eosinophils in the infiltrate, the capillary engorgement and the serohemorrhagic edema of the dermis, indicate that the unusual manifestations of the disease may have had an allergic basis. A previous erysipelothrix infection of localized character probably induced the hyperergic state. Intensive treatment with penicillin effected recovery.

Actinomycosis Due to Nocardia Asteroides.—According to Kirby and McNaught infections in man due to the aerobic, partially acid fast Nocardia asteroides are rare as compared to those due to the anaerobic Actinomyces bovis. The symptoms, course of the disease and response to therapy are so nearly alike that the disease produced by the two types of fungi should be called actinomycosis. The mortality of Nocardia asteroides is high, as is indicated by the fact that in 28 of the 32 cases collected from the literature death had occurred when their reports were published. The infection was pulmonary in 28 cases, and the brain was the site of metastasis in at least 10. Two new cases of infection with N. asteroides are added in this report. It is recommended that patients with actinomycosis due to the aerobic N. asteroides be treated with the sulfonamide compounds and penicillin as vigorously as are those infected with the anaerobic Actinomyces bovis and that surgical drainage, iodides and roentgen therapy be used as the indications arise.

Streptomycin in Intestinal Infections.—Pulaski and Amspacher used streptomycin in 8 cases of bacillary dysentery. Two were due to Salmonella, 1 to Shigella sonnei and the remainder to various subtypes of Shigella flexneri. Beneficial effects are obtained by the use of streptomycin orally or parenterally in infections found resistant to the sulfonamides. Doses of 1 to 4 Gm. for periods ranging from three to sixteen days are effective in most cases; the larger amounts are recommended to minimize the risk of the development of streptomycin resistant organisms. Since the offending bacteria are not confined to the lumen of the bowel but may penetrate into deep crevices and mesenteric lymph nodes, it is recommended that the combined oral and parenteral routes be used

Penicillin in Acute Throat Infections.—Faucett and his associates discuss the therapeutic measures used in the treatment of 561 cases of acute infections of the throat. Penicillin ice cream, 25,000 units every three hours, has been offered as a therapeutic measure for the treatment of acute tonsillitis, pharyngitis, scarlet fever throats and Vincent's infections of the throat and mouth. This method of administration may be used for other infections caused by organisms susceptible to penicillin. Streptococcus antitoxin serum 18,000 units followed by penicillin ice cream 25,000 units every three hours for five to seven days has been recommended as the treatment of choice for scarlet fever. Massive parenteral doses of penicillin without surgical intervention is preferred for proper management of peritonsillar abscess unless spontaneous drainage is imminent. Penicillin parenterally and sulfonamides intravenously (later orally) are recommended for certain overwhelming and fulminating infectious diseases, including those of the throat.

Lower Nephron Nephrosis.—Lucké points out that a syndrome characterized by oliguria or anuria, heme pigment excretion, azotemia, hypertension and uremia may develop in conditions associated with destruction of tissue or intravascular hemolysis. This syndrome has been observed in crushing injury and other forms of trauma to muscle, nontraumatic muscular ischemia, uteroplacental damage (and eclampsia), burns, transfusion with incompatible blood, blackwater fever and other types of intravascular hemolysis, heat stroke, sulfonamide intoxication, alkalosis, mushroom poisoning and some other kinds of poisoning with vegetable and chemical agents. Death usually occurs within ten days. This syndrome has been the most frequent form of fatal kidney disorder encountered among military personnel during the war. The author reviews the records of 538 fatal cases received at the Army Institute of Pathology. The essential changes are selectively restricted to the lower segments of the nephrons and comprise focal degeneration or necrosis, presence of heme casts, secondary inflammatory reactions in the surrounding stroma and thrombosis of thin walled veins. The term lower nephron nephrosis is suggested as descriptive of the location and nature of the morphologic changes.

Fatal Pulmonary Embolisms in 100 Battle Casualties.—The 100 cases of fatal pulmonary embolism reviewed by Hamilton and Angevine occurred in battle casualties, that is, in young, previously healthy men and thus permitted observations without the usual variables and complicating factors of age and vascular disease. Venous stasis, caused most frequently by immobilization, appears to be the most important factor in the production of phlebothrombosis. Pulmonary infarcts were located predominantly on the right side and in the lower lobes. The prevalence of venous thrombosis on the left side of the body did not have a direct relationship to trauma, which occurred more frequently on the right side. The distribution of the venous thrombosis seems to be based on the anatomic relationships at the level of the common iliac vein.

Bronchial Adenomas.—The study reported by Holley is based on records and specimens of 39 cases of bronchial adenomas. In 38 cases the predominant symptoms and signs were cough, hemoptysis, recurrent acute respiratory infection and expectoration. Roentgenographic features were those of atelectasis, bronchiectasis, pulmonary inflammation, bronchial blockage and presence of a mass. These signs and symptoms were not all present in the same patient. The tumor was found incidentally at necropsy in 1 additional case. The tumors were located at or near the pulmonary hilus, were usually polypoid, and in several cases attained rather large size. They assumed two distinct patterns, one which simulated that of appendical carcinoid and the other that of some of the mixed tumors of salivary glands and other structures of the mouth and face. They have been designated carcinoid type and mixed tumor type of bronchial adenoma respectively. This study indicates that lobectomy or pneumonectomy, according to the location of the tumor, is the preferred treatment.

Pathology of Acute Falciparum Malaria.—Pathologic lesions observed in 50 cases of fatal falciparum malaria are discussed and correlated with available clinical information. Selective localization of parasitized erythrocytes does not occur outside the bone marrow, liver and spleen; the presence of "plugged" parasitized vessels in an organ cannot be correlated with clinical symptoms. Cerebral symptoms are considered to be related to anoxia. Thrombosis of the cerebral vessels is frequent, causing hemorrhages and the so-called granulomas. Renal lesions, both diffuse glomerulonephritis and hemoglobinuric nephrosis, occur with relative frequency and are, together with the myocardial infiltrate and adrenal "atrophy," evidence in favor of circulating toxins or allergens, probably released by Plasmodium falciparum.

Topical Sodium Fluoride in Dental Caries.—Knutson and Armstrong present data on the incidence of dental caries in the permanent teeth of fluoride-treated children for a three year period and for the third year of a longitudinal study. The investigations were made in urban communities in Minnesota. When the study was begun, the children ranged in age from 7 to 15 years. The treated group consisted originally of 337 children, and the control group included 392 children. The former group received applications of sodium fluoride to the teeth in the upper and lower left quadrants, the teeth in the upper and lower right quadrants serving as controls. The control group of children did not receive fluoride treatments. During the three year period that ended in May 1945 the number of permanent teeth initially attacked by caries was 36.6 per cent less in fluoride treated than in untreated teeth. This percentage difference is somewhat smaller than that observed for the first year (39.8) and for the two year period (41.4). During the third study year, which ended in May 1945, the initial caries attack was 22.2 per cent less in fluoride treated than in untreated permanent teeth. This yearly difference is substantially less than that observed for the second year, 46.6, and for the first study year, 39.8. Among permanent teeth which were carious at the beginning of the study in 1942 the number of additional surfaces which became carious during the three year period that ended in May 1945 was 23.9 per cent less in treated than in untreated carious teeth. The percentage difference observed for the first study year was 12.4 and for the first two year period was 23.1. By individual study years there were 12.4, 25.2 and 33.1 per cent less newly carious surfaces in fluoride treated than in untreated carious teeth for the first, second and third years respectively.

Taste and Food Selection in Hypoglycemia.—This report by Mayer-Gross and Walker is based on 202 experiments carried out in 100 subjects with the object of testing self regulation in different stages of hypoglycemia. The subject was offered a choice of five liquids: water, 5 per cent sucrose, 30 per cent sucrose, 0.5 per cent sodium chloride and saccharin; his preference, judgment of taste and other reactions were noted and his blood sugar determined. The most important result was the preference for 30 per cent sucrose solution below the blood sugar level of 50 mg. per hundred cubic centimeters and the rejection of it above this critical level. Other findings, such as the judgment of sweetness for 5 per cent sucrose and saccharin, were also found related to the blood sugar level. The results are discussed in the light of the principle of self regulation.

Anergy in Infants' Skin to Diphtheria.—Wright and Clark point out that the reactions of mothers and their newborn infants to the Schick test often differ and that the disagreement is due almost entirely to the failure of the diphtheria toxin to excite a positive response in many infants of Schick positive mothers. This lessened skin reactivity, which in its extreme form has been termed "anergy," was present in more than one third of the infants of Schick positive mothers examined in five surveys, which are listed by the authors. They record the results of some experiments that they have made to find out in what ways the reactions caused by various irritants and by histamine in the skins of newborn infants differ from those in adults. They conclude that the low reactivity of newborn infants' skins to diphtheria toxin is not due to insensitivity to histamine or to inability to exhibit the typical triple response on injury. Since similar anergy is found in other forms of delayed response at this age, such as that produced by ultraviolet light, the mechanism underlying these responses may differ from that concerned with immediate reactions and may not become fully functional until some weeks after birth. It seems likely, however, that the lesser skin reactivity seen in delayed reactions in infants is partly due to the relatively rich and superficial vasculature of their skins, which would facilitate the escape both of injected substances and of vasodilator products of injured tissues.

Febrile Headache.—Scott and Warin studied the clinical characteristics and mechanism of headache accompanying acute febrile illness in 100 patients admitted to a military hospital in the Middle East. Evidence is presented indicating that in febrile headache pain arose from distention of the walls or perivascular tissues of dilated cranial arteries. Eye ache which accompanied headache in 93 patients was probably due to an orbital vascular disturbance.

Examination of Home Contacts of Tuberculous Persons. W. P. Dick and B. C. Thompson.—p. 791.
*Hypertension and Calcium Intake. C. M. Kesson and A. McCutcheon. —p. 793.

Oral Penicillin in Gonorrhea.—Bushby and Harkness say that of 62 patients treated for fifteen hours with six doses each of penicillin 40,000 units and sodium citrate 1 Gm. given by mouth, a total of 240,000 units, 2 relapses occurred. This rate compares favorably with their experience in parenteral therapy. It is important to keep strictly to the regular dosage schedule and the restriction of fluids to 1½ pints (0.75 liter) during the course of treatment.

Folic Acid for Pernicious Anemia.—Harrison and White describe the result of folic acid therapy of a man aged 63 with pernicious anemia. Folic acid was given by mouth. On each of the first two days 20 mg. was given, followed by 10 mg. daily for six days. On the day after the start of therapy the patient's general condition deteriorated. A slow drip transfusion of 250 cc. of packed red cells was given carefully for six hours, followed by distinct improvement. A further 250 cc. of packed red cells was given next day. The general condition was now much improved. Therapy led to a return to normal hemopoiesis, as shown by the changes in sternal marrow and peripheral blood. Repeated doses of folic acid were necessary to maintain normal hemopoiesis.

Hypertension and Calcium Intake.—Kesson and McCutcheon did not find evidence that a high retention of lime prolonged over many months has any effect on the development of hypertension or on the calcification of the vessel walls.

Methionine in Treatment of Anemias.—Gajdos produced severe carbon tetrachloride poisoning in rats. Parenteral or oral administration of methionine prevented the occurrence of severe anemia in these animals. These results were confirmed in a second series of animal experiments in which anemia was produced in rats by a diet deficient in methionine, while anemia did not occur in rats on the same diet to which methionine was added. Ten patients between the ages of 48 and 70, with anemia of various types, were given 1 to 2 Gm. of methionine divided into four to eight cachets daily for two to four weeks. There was no untoward reaction and a pronounced improvement in the erythropoiesis of 7 patients, 3 with normocytic or hypochromic anemia secondary to hepatic cirrhosis, late untreated syphilis and duodenal hemorrhage, respectively, 1 with severe nutritional anemia, 1 with macrocytic anemia and 2 with normocytic anemia of unknown origin. Methionine was ineffective in 2 patients with pernicious anemia and in 1 with anemia secondary to diaphragmatic hernia. The slow and continuous increase in the number of red blood corpuscles with an average increase of 1,100,000 in two weeks may be explained partly by the amino acid character of the methionine and by its favorable effect on hepatic function.

Fracture of Femoral Neck Following Roentgen Irradiation of Uterine Cancer.—Kulseng-Hanssen gives a brief survey of the damage to the bony structures caused by irradiation, giving particular attention to spontaneous fracture of the femoral neck. In 1 patient the fracture was bilateral and in 3 others unilateral. All 4 patients had received irradiation to the anterior and posterior fields and not to the lateral fields. The dose of radiation had been four times 2,300 units and four times 3,000 units. The fractures occurred from six to eighteen months after treatment. Two of the patients complained of pain some months before the occurrence of the fracture. The pain was moderate; all patients remained up and about. Osseous healing occurred in four fractures after a long time. One patient died of cancer.

*Methylthiouracil Treatment of Hyperthyroidism. A. Rune Frisk.—p. 1575.

Methylthiouracil Treatment of Hyperthyroidism.—Frisk reports that the thyrotoxic symptoms disappeared in 101 of 104 cases of hyperthyroidism treated with methylthiouracil or allied substances. Of the 101 patients 8 were operated on. Of the 24 who completed treatment 17 have been without symptoms for over six months. No certain relation between the severity of the hyperthyroidism and the rapidity of improvement was demonstrable. The advisability of the treatment during pregnancy is questioned. The danger of agranulocytosis during long continued treatment is slight, but regular close control of the patient for a long time is called for. To what extent methylthiouracil treatment can cure hyperthyroidism is not yet known. In its present form the treatment complements surgical treatment. Certain types of hyperthyroidism should be treated operatively. Patients with hyperthyroidism with considerable enlargement of the thyroid, of toxic adenoma and intrathoracic goiter react slowly to methylthiouracil, and there is danger of considerable enlargement of the thyroid gland. The time factor requires operative treatment of other moderately grave to grave cases of thyrotoxicosis with palpably enlarged thyroid gland. In mild cases without enlargement of the thyroid as well as in recurrence after operation and in cases with cardiac or other complications thiouracil treatment alone should be applied.

Book Notices

Peripheral Vascular Diseases. By Edgar V. Allen, B.S., M.A., M.D., Associate Professor of Medicine, Mayo Foundation, Graduate School, University of Minnesota, Minneapolis, Nelson W. Barker, B.A., M.D., M.S. in Medicine, Associate Professor of Medicine, Mayo Foundation, Graduate School, University of Minnesota, and Edgar A. Hines Jr., M.D., B.S., M.A., Associate Professor of Medicine, Mayo Foundation, Graduate School, University of Minnesota. With Associates in the Mayo Clinic and Mayo Foundation. Cloth. Price, $10. Pp. 871, with 386 illustrations. W. B. Saunders Company, West Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, 1946.

Peripheral vascular disease to many physicians is a mysterious catchall into which diagnostic problems are discarded in haphazard fashion. To bring order from this chaos is a noteworthy purpose and a goal toward which these authors have made a splendid effort. This scholarly, well documented and scientific presentation of a difficult subject deserves an enthusiastic welcome.

The book begins with a review of gross and fine anatomy of the vascular system, after a preliminary glossary of common clinical terms. In a chapter on methods of investigation, accepted technics are thoroughly reviewed as to value, utility and accuracy. The writers frankly state whether any method is preferred and what their experience, if any, has been with it. In the assay and management of peripheral vascular diseases certain procedures are of theoretical value, and the practical applications and reliability factors are analyzed in the light of the experience at the Mayo Clinic. The various diseases of the vascular periphery are dealt with in subsequent portions, including Raynaud's disease, erythromelalgia, sudden occlusions, arteriosclerosis, Buerger's disease, periarteritis, scleroderma, aneurysms, thrombophlebitis and varicose veins. Preceding many of the special sections is a brief illustrated historical sketch of a pioneer contributor to the subject, which is a highly interesting and commendable feature. The material is well organized according to a pattern outlined in each chapter subheading. Illustrations are well chosen and frequent enough to enhance the value of the text. Bibliographic references follow each topic and are of both current and historical significance. Primarily the entire book is written from a medical point of view, but there are brief contributions by several surgeons of the clinic which allow adequate survey of their field.

The chapter on arteriosclerosis is especially noteworthy and almost a must for every physician. The analysis of the types of pain encountered in arteriosclerosis obliterans, succinctly stated, is masterful. The use of the term "secondary Raynaud's phenomena" is perhaps unfortunate because it is likely to be confusing. The experience of military surgeons on the secondary effects of trauma on the peripheral vascular system will require more thorough analysis. The increasing use of paravertebral sympathectomy and sympathetic block in the management of painful wounds, Sudeck's syndrome and allied conditions was one of the great lessons of war surgery. Future editions will probably contain more thoroughly digested data concerning the reflex effect of trauma on the peripheral vascular system via the autonomic nervous system.

This book can be recommended to all who are interested in the subject, and this applies to every physician and surgeon.

Mongolism and Cretinism: A Study of the Clinical Manifestations and the General Pathology of Pituitary and Thyroid Deficiency. By Clemens E. Benda, M.D., Director, Wallace Research Laboratory for the Study of Mental Deficiency, Wrentham, Massachusetts. Fabrikoid. Price, $6.50. Pp. 310, with 103 illustrations. Grune & Stratton, Inc., 443 4th Ave., New York 16, 1946.

This monograph by Dr. Benda, as indicated by its title, implies that mongolism and cretinism are endocrine diseases of a similar nature but due to abnormalities of different glands. However, the contributions made by the author and the amount of space assigned in the text definitely show his interest to be primarily devoted to the problems of mongolism. In his preface he states that "the purpose of the book is to rid mongolism of the mystery clouding its proper medical recognition and to publish data . . . devoted to the study of mental deficiency, during ten years of continuous research." He has studied more than 300 mongoloid patients, many of them over a ten year period, performed fifty necropsies and made intensive studies of measurements, roentgenograms and biochemical and psychologic data. In addition, he has provided much new material on family history and hereditary backgrounds and on the relationship of mongolism to the pregnancy of the mother and the order of birth in the family. On these grounds alone the book has made a decided contribution to medical knowledge about this tragic condition and the author has fulfilled his stated objective.

The controversial theme is struck by his decided conviction that mongolism is due to a type of anterior pituitary deficiency which is as sharply defined as is thyroid deficiency in cretinism. The acceptance of this thesis by the individual reader will probably depend on his readiness to accept the evidence as valid and on his ability to fit the hypothesis with his own experience in handling mongoloid patients. The evidence as presented leaves many gaps of information which would have to be filled in before the pathogenesis of mongolism could be explained on an endocrine basis alone.

From the point of view of therapy one important element was omitted or too lightly touched on. That is the fact that such patients can be adequately treated only in an institution. Attempts at psychologic or endocrine treatment in the home are well-nigh impossible and, as a matter of fact, the presence of a mongoloid child in a family almost always disrupts the group either through divorce of the parents or through gross neglect of other siblings. It is to be feared that efforts to cure this as yet incurable condition by endocrine means will increase the number of such patients kept in their homes, with the obvious expectancy of more and more family maladjustments and disappointments. Furthermore, by his suggestion that obstetricians might be able to prevent the birth of mongoloids by observing the history of pregnancy, abortion and maternal endocrine situations, Dr. Benda has saddled obstetricians with a responsibility which rests on a very tenuous basis. It will probably take much more information than is now available before treatment during pregnancy can be put on a sound scientific basis. Most important of all, it is felt that information to the public on this subject may lead to a great deal of fear and confusion of mind. We have not yet reached a point in our understanding at which we can settle the fears of laymen or answer their questions. Nevertheless this book is a distinct and valuable addition to our medical knowledge and does contribute to our understanding of one of the most perplexing problems of the day. That Dr. Benda does not answer all our questions is true, but to have added to our factual material and to have turned our sights to a new approach to the subject is perhaps enough for one book.

Carbohydrate Metabolism: Correlation of Physiological, Biochemical and Clinical Aspects. By Samuel Soskin, M.D., Director of the Research Institute, Michael Reese Hospital, Chicago, and Rachmiel Levine, M.D., Director of Metabolic and Endocrine Research, Michael Reese Hospital. Cloth. Price, $6. Pp. 315, with 75 illustrations. University of Chicago Press, 58th St. and Ellis Ave., Chicago 37, 1946.

In the latter part of this book the authors emphasize the fact that newer research enforces the view that beyond a certain point the fats, carbohydrates and proteins have a common pathway of metabolism. One is not justified, therefore, in discussing the chemical transformations of one of the major foodstuffs in the body to the exclusion of the others. This broad attitude sets the pattern for the entire book. The authors, who have carried out extensive investigation in the field of carbohydrate metabolism, point out that the evidence on which the current concepts are based has been assembled through a variety of experimental devices—studies on intact animals, tissue slices, tissue press juice and micro-organisms—and that as a result one cannot view the story of carbohydrate metabolism as complete or even satisfactory in all the details at the present time.

The first section in the monograph deals with the chemical changes which carbohydrate undergoes under enzymatic influence in the body, the role of phosphate and the resultant energy transformations. There follows a searching critique of the factors bearing on the classic concept of diabetes; the positive role of the liver in carbohydrate metabolism is reaffirmed. The part played by the various hormones is clearly outlined, and the integration of these factors in metabolism is presented. Of the function of insulin it is stated that it "enables the liver to do at low or normal blood sugar levels that for which very high blood sugar levels are required in the absence of insulin." The application of basic principles to clinical use and variations of carbohydrate metabolism in different species are touched on. The discussion throughout is clear and cogent, with helpful diagrams and tables. At the end of each chapter there is an extensive list of references to the literature discussed in the text. A tendency to oversimplification is justified by the effort to establish a clearcut picture as a basis for further development. The clinician will find no rule of thumb aids on treating his diabetic patients in this book; instead he will discover, outlined with textbook clarity, the principles on which effective treatment is based.

The Surgical Technic of Abdominal Operations. By Julius L. Spivack, M.D., LL.D., Associate Professor of Surgery, University of Illinois College of Medicine, Chicago. Fourth edition. Fabrikoid. Price, $10. Pp. 710, with 682 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1946.

This is a well known work on surgical technic, and its favorable reception by physicians is evidenced by the appearance of the fourth edition. It is difficult to estimate its worth and place it properly in the surgeon's library. The emphasis on historical aspects requires special mention because the average surgeon frequently does not know who originated what operation. On the other hand, the careful historical development of a procedure which has long been discarded is going to prove of doubtful benefit to the reader. This manner of presentation can be overdone, and the detailed eponymic description of the thirty-two methods of gastrostomy listed could better be abbreviated. There are described eight methods of performing hepatopexy, now rarely done. The mere statement that some one described such a method in such a year is not enlightening. Thus the background of Billroth's original gastric operations and the amount of experimental work and thought preceding them are far more interesting than the actual fact that he and his associates deserve priority. In introducing an operation for ventral hernia, the author says:

> The priority of introducing this method belongs to Sapjieko, who performed it for the first time in 1898 and published it in February 1900. Independently of Sapjieko, it was described by Piccoli in January 1900. Thus the priority in reporting belongs to Piccoli and of performing to Sapjieko. In the United States it is known as the Blake method.

All of which doesn't really contribute to the advancement of surgical knowledge.

Operations on the stomach are allotted a prominent portion of the text, whereas operations of the left colon, sigmoid and rectum are less fully enlarged on. It may be remarked that there are many valuable technics (and interesting eponyms) deserving of mention which are associated with these anatomic areas. The chapters devoted entirely to technic are very good and will benefit any surgeon. The extensive bibliography of original articles is quite useful. The illustrations are superior in quality and will educate every physician.

A Primer for Diabetic Patients: An Outline of Treatment for Diabetes with Diet, Insulin and Protamine-Zinc Insulin, Including Directions and Charts for the Use of Physicians in Planning Diet Prescriptions. By Russell M. Wilder, M.D., Ph.D., F.A.C.P., Professor and Chief of the Department of Medicine of the Mayo Foundation, University of Minnesota, Rochester, Minnesota. Eighth edition. Cloth. Price, $1.75. Pp. 192, with 8 illustrations. W. B. Saunders Company, West Washington Square, Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W. C. 2, 1946.

This sensible primer, with comparatively few changes, is now in its eighth edition. If diabetic patients would only learn the answers to the admirable questions at the end of each chapter, their lives would be greatly prolonged.

In these days of intravenous medication it is a bit surprising that so much emphasis is put on the administration of dextrose by rectum instead of by vein when food is not retained (page 47). The subheading of the tables for the average height, weight and age for men and women is incorrect, because the tables were designed for men and women as ordinarily dressed (pages 158-159). "We usually advise against increasing the dose of protamine-zinc insulin to an amount larger than 20 units" (page 29). Certainly many patients can take more with impunity. The directions for giving mixtures of protamine zinc insulin and soluble insulin are excellent, but they occupy nearly four pages of the book, thus demonstrating the complications of administration (pages 30-34). Globin insulin, sulfadiazine and penicillin are not mentioned, and the advantages of price and ease of purchase of isopropyl alcohol are not sufficiently stressed.

Proceedings Conference on the Rehabilitation of the Tuberculous. *Sponsored by the Office of Vocational Rehabilitation, Federal Security Agency,* with The Tuberculosis Control Division, U. S. Public Health Service, Federal Security Agency, and The National Tuberculosis Association, March 4-6, 1946, Washington, D. C. Edited by Holland Hudson, Director, Rehabilitation Service, National Tuberculosis Association, and Norvin C. Kiefer, M.D., Surgeon, Office of the Chief, Tuberculosis Control Division, U. S. Public Health Service. Paper. Pp. 138. National Tuberculosis Association, 1790 Broadway, New York 19, 1946.

In March 1946 two federal agencies and one national voluntary health agency held a conference in Washington to discuss the various skills which will contribute substantially to the rehabilitation of tuberculous patients. In the planning for this three day meeting the Office of Vocational Rehabilitation was sponsor, and the co-sponsors were the Tuberculosis Control Division of the U. S. Public Health Service and the National Tuberculosis Association. Physicians, nurses, occupational therapists, social workers and counselors were invited to define and clarify the functions of each of these assignments as they relate to the rehabilitation of the patient.

The topics covered by the proceedings of the conference are the purposes of the conference; editors' foreword; participating members; guests; functions of the nurse, of the social worker, of the educational counselor and of the occupational therapist in the rehabilitation of the tuberculous; function of the rehabilitation counselor in the federal-state program for the vocational rehabilitation of the tuberculous; terminology of rehabilitation of the tuberculous, and recommendations for plans to solve some of the unsolved problems of rehabilitation of the tuberculous.

The editors have steered a midway course between formal summarization and full transcript. The flavor and color of discussion have been retained along with the essence of the study. It is apparent from the text that the invitations to participate were addressed to articulate and inquiring minds. Many of the participants exhibit a warm enthusiasm for the special skills of their personal experience, an understanding of the objectives of other types of work and a wish to coordinate total effort for the benefit of the tuberculous patient and his family. Throughout the discussion, comments and suggestions were made in terms of the local area and the individual hospital as well as for the nation as a whole.

De osteopetrosis en de normale osteoen hæmatopoïese: Osteopetrosis, ziekte van Albers Schönberg, marmerbeenziekte, osteosclerosis fragilis generalisata, congenitale osteosclerose. Door Dr. K. Dierickx. [Osteopetrosis and Normal Osteo- and Hemato poiesis: Osteopetrosis, Albers-Schönberg Disease, Marble Bones Disease, Osteosclerosis Fragilis Generalisata, Congenital Osteosclerosis.] Universiteit Gent, proefschrift ter verkrijging van den Graad van Geaggregeerde van het Hooger Onderwijs in de Pathologische Ontleedkunde. Paper. Pp. 148, with 59 illustrations. Uitgeversbedrijf Fiat, Ghent, Belgium, 1944.

This monograph records clinical studies and the roentgenographic, histologic and chemical study of the bones of 2 patients dying with osteopetrosis. A previously nonrecorded feature was the discovery of conical structures in practically all the bones. A technic is described to demonstrate these cones by roentgen ray examination. The conical structures are considered to be the result of the absence of or partial lack of resorption of the cartilage and endochondrial or membrane bone. The retardation of bone resorption is accompanied by generalized fibrosis of the marrow with hypoplasia of the blood vessels and resultant aplasia of the marrow and extramedullary hematopoiesis. The disease is characterized as a recessive hereditary morbid condition, the onset coinciding with the first appearance of ossification, about the second fetal mouth. The bibliography includes one hundred and sixty items.

Handbook of Neurological Examination and Case Recording. By D. Denny-Brown, M.D., J. Jackson Putnam Professor of Neurology, Harvard Medical School, Boston. Paper. Price, $1.75. Pp. 107. Harvard University Press, Cambridge 38; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This book, bound loosely by wire rings, is a printed form of material originally written for House Officers of the Neurological Unit of the Boston City Hospital. It resembles many similar manuals used in hospitals. These outlines can hardly replace chapters in standard textbooks available to all students, residents and physicians, for they are sketchy and lack the usual tables and illustrations.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

RH FACTOR

To the Editor:—A woman aged 26 has had four pregnancies. The first child, born eight years ago, lived to the age of 4 and died of burns. The second one, eighteen months later, lived to the age of 8 months and died of causes unknown to me. The third and fourth children died in their first week of life from erythroblastosis fetalis, diagnoses established by competent specialists. The woman is Rh positive. She is anxious to have more children if she can be assured that they will not die from erythroblastosis fetalis. Can she have normal babies in the future?
M.D., California.

Answer.—The Rh factor is not a single homogeneous substance. It consists of several qualitatively differing Rh types. The term Rh positive is a collective general designation.

An Rh-positive woman of one type may become sensitized by the Rh factor of her baby of a different type, and sensitization may be the cause of fetal erythroblastosis.

The following questions have to be answered in the case described in the query:

1. Was the erythroblastosis due to Rh incompatibility? This may be answered by testing the Rh type of the husband and wife. If they differ, tests for Rh antibody in the blood of the mother may prove sensitization. Examination should include tests for anti-Rh saline agglutinins, serum-albumin agglutinins, blocking antibody, the Diamond-Abelson slide test and the Coombs test (Hill's developing test). If one or more of these tests are positive, Rh sensitization is established. The degree of sensitization may be demonstrated by titration of the antibody.

In an occasional case sensitization and erythroblastosis may be due to the Hr factor, which is shown by the presence in the mother's serum of agglutinins clumping all Rh-negative red cells and some Rh-positive (heterozygous) cells.

2. If the father is Rh positive, is he heterozygous or homozygous Rh-positive? This is an important question because, if he is heterozygous, some of his children may be Rh negative and not subject to erythroblastosis caused by Rh incompatibility.

There are two ways to answer the problem:

(*a*) Testing of the father's blood with an anti-Hr serum. Clumping suggests that the father's blood is heterozygous. Negative results suggest homozygosity.

(*b*) Rh testing of the parents of the husband and of living children, if any. If any of them is Rh negative, heterozygosity of the husband is shown.

All children of a homozygous parent must be Rh positive and therefore more likely affected by the disease.

If the Rh factor is excluded as the cause, there is still the possibility that factors A or B may be responsible if present in the fetus and absent in the mother.

These studies may throw light on the cause of the disease and permit a cautious prognosis, but the mother cannot be assured that her child will not have erythroblastosis and still less that it will not die from the disease.

Transfusions with Rh-negative blood have reduced the mortality from erythroblastosis fetalis considerably.

Artificial insemination from a properly selected donor is the only sure way of having a normal baby by a woman who has had babies with erythroblastosis due to blood group or Rh incompatibility.

PILOCARPINE AND SEBORRHEA

To the Editor:—Pilocarpine has been advised in a number of prescriptions for the treatment of seborrhea. What is the effect of pilocarpine on the sebaceous glands? While pilocarpine increases sweating in general, is its effect locally and systemically to inhibit the activity of the sebaceous glands in general?
Harold Simons, M.D., Bremerton, Wash.

Answer.—Sollmann (A Manual of Pharmacology, ed. 4, Philadelphia, W. B. Saunders Company, 1932) does not list the sebaceous glands as influenced by pilocarpine. This drug was much used years ago in formulas employed for seborrhea or dandruff. Modern remedies rarely include it. It probably does not have any effective action in diseases of the scalp.

SUDEK'S BONE ATROPHY

To the Editor:—A woman aged 54 "turned" on her left ankle in October 1943. The pain disappeared after eight months' rest. X-ray studies disclosed osseous rarefaction in the region of the left ankle. In January 1944 the left knee became swollen and painful. An orthopedist advised the patient to "use it," as atrophy from disuse was present. This only aggravated the symptoms. The patient then resorted to resting the knee, which caused great improvement. Physical therapy, various medicines and procaine injection have been tried, but the patient still has slight pain in the knee, which is greatly increased by even slight movement. Is excision of the patella indicated for this condition of painful knee?
M.D., Illinois.

Answer.—It is probable that the patient described in the query has an unusual and unaccountable type of bone atrophy sometimes called Sudek's bone atrophy. Excision of the patella should be limited to certain types of fractures and to those rather rare cases of osteoarthritis of the knee in which the patella seems to be the chief offender. Although people can get along well without the patella, it should not be removed indiscriminately. Sudek's bone atrophy has a slow course, which is often several years. Time worn remedies such as heat, massage and use to the point of toleration do help. The diet should be scrutinized to see that the patient is getting the proper food. Sometimes in elderly patients, particularly women who are living alone, the diet may be improperly balanced.

ETHYLENE DICHLORIDE

To the Editor:—What are the toxic effects of ethylene dichloride used commercially as a finisher on celluloid products? Would any by-products be produced by the action of ethylene dichloride on the acetate? A patient who works with these chemicals complains of nausea and weakness for several hours after contact with the fumes. His liver is palpable about 2 inches below the costal margin. Tests of hepatic function have not been performed.
Isadore M. Siegel, M.D., Far Rockaway, N. Y.

Answer.—Ethylene dichloride alone is capable of causing the manifestations described in the query. Ethylene dichloride (dichloroethane) is one of the highly toxic members of the chlorinated hydrocarbons. Nausea, vomiting, headache and drowsiness represent initial features of toxic action after sufficient exposure. Greater exposure in terms of time and concentration may lead to involvement of the liver, kidneys, lungs, adrenals and corneas. The upper limit of safety possibly lies between 100 and 200 parts per million. A recent publication by Heppel, Neal, Perrin, Endicott and Porterfield (*J. Indust. Hyg. & Toxicol.* **28**:113, 1946) deals with the effects of daily inhalations. This is the fifth in a series on 1,2-dichloroethane and includes an extensive bibliography.

KIRSCHNER ELECTROCOAGULATION OF GASSERIAN GANGLION

To the Editor:—In the following article reference is made to Kirschner's electrocoagulation method for treating gasserian ganglion. Of what does the method consist? Has it met with approval in the United States?

> "*ELECTROCOAGULATION OF GASSERIAN GANGLION*
>
> "*B. Oddsson*
>
> "In the neurosurgical department of Rigshospitalet in Copenhagen 86 patients with trigeminal neuralgia have been treated during the last six years with electrocoagulation of the gasserian ganglion by the Kirschner method. The operation takes a few minutes. The patients were between the ages of 19 and 92. There were 54 women and 32 men. The duration of the neuralgia was on an average six years, the longest thirty years and the shortest three months. Primary relief of symptoms was obtained in 66 cases, the remaining 20 having to undergo other treatment. The longest follow-up was fifty-one months, the shortest three months. The follow-up revealed that 25 patients were relieved of pain and 7 were substantially improved; 13 patients had a recurrence, which in most cases yielded to a repeated electrocoagulation. There were no fatal cases. Abst. from *Acta Psychiatrica et Neurologica*, Copenhagen 19:1-411 (Nos. 1-2) 1944."

C. B. Greear, M.D., Honaker, Va.

Answer.—Kirschner's method of treating trigeminal neuralgia by electrocoagulation of the gasserian ganglion has never found acceptance in this country. This method of electrocoagulation is a blind one and unsatisfactory for several reasons. It is impossible to determine with accuracy which divisions of the gasserian ganglion are being coagulated or even of being sure that the ganglion is being treated. Furthermore, it is impossible to limit the coagulation accurately to the structures desired. In contrast, retrogasserian neurotomy, which is commonly practiced by neurosurgeons of this country affords good relief with a mortality of less than 0.5 per cent. The results of electrocoagulation by the method quoted in the query are not as favorable as the results of surgery.

SCLERODERMA

To the Editor:—What is the latest treatment of scleroderma?

Lawrence L. Garner, M.D., Milwaukee.

Answer.—Living in an equable, warm climate is helpful in the treatment of scleroderma. Physical therapy is useful including massage, heat and contrasting baths and percutaneous electrical transmission of mecholyl. Large enough doses of vitamin D to achieve a negative calcium balance have been recommended by Cornbleet and the use of preparations of pancreas by Seller. Thyroid has been found helpful in some cases, as well as posterior pituitary injection. O'Leary and Waisman recommended neostigmine. Gold salts as well as bismuth preparations have been tried. A number of reports praising the effectiveness of bismuth for localized scleroderma have appeared. It is hoped that this agent will prove as useful in the generalized variety. Surgical intervention has been both lauded and condemned. Sympathectomy and parathyroidectomy have been followed by rapid improvement. It appears, however, that these favorable responses are but temporary.

PROLONGED INTERVAL BETWEEN PREGNANCIES

To the Editor:—Is there any factual basis to support the belief that a second pregnancy may be especially hazardous after an interval of fourteen years? The first pregnancy was normal but was complicated post partum by a breast abscess. The woman is now 36 years of age, in good health and without any pelvic abnormality.

M.D., New Jersey.

Answer.—The length of the interval between pregnancies does not have an appreciable effect on a subsequent pregnancy. The hazard of a second pregnancy fourteen years after the first one is not increased provided there has not been a change in the patient's physical condition. However, age is an important factor in childbearing. Older mothers are more likely to have hypertension, vascular-renal disease and other physical handicaps which may complicate pregnancy.

TREATMENT OF PULMONARY EMBOLISM

To the Editor:—A white woman aged 28 had a typical attack of pulmonary embolism on the tenth day following pelvic surgery. The pulmonary embolism was accompanied with signs of severe shock, including profuse perspiration, clammy skin, profound fall of blood pressure and a rapid, scarcely palpable, pulse. What is the treatment of shock in such a case? Is there any objection to stimplants such as epinephrine, caffeine or metrazol? Can stimulants dislodge the first embolus or cause additional embolic attacks?

M.D., California.

Answer.—Shock following pulmonary embolism is due to mechanical obstruction of the pulmonary circulation which in many fatal and unusually severe cases involves both the right and left pulmonary arteries by means of a "saddle embolus." Reflex nervous phenomena may contribute harmful effects, perhaps through distention of the artery by the embolus. It is interesting that shock and harmful reflexes do not occur when the pulmonary artery is surgically ligated in the course of pneumonectomy.

The most useful immediate treatment of pulmonary embolism consists in hypodermic injection of morphine and inhalation of a high concentration of oxygen by catheter, tent or mask. The stimulants ordinarily used in the treatment of so-called surgical shock are not likely to be of value in pulmonary embolism and may prove harmful when the right side of the heart is overloaded. Papaverine has been recommended for the reflex nervous phenomena that may be present. If the patient survives the immediate attack, heparin or Dicumarol (3-3'-methylene-bis-[hydroxycoumarin]) should be given intravenously to prevent propagation of thrombi, and the thrombosed vein that was the source of the embolus should be ligated on the cardiac side of the thrombus. An emergency operation to remove the pulmonary embolus after incision of the pulmonary artery in severe cases has been successful in a few instances.

ADMINISTRATION OF THYROID

To the Editor:—Is there any advantage in prescribing thyroid in divided daily doses rather than in a single daily amount?

M.D., New York.

Answer.—The action of desiccated thyroid is so prolonged that there is no advantage whatever in prescribing the daily dose in divided portions. It works just as well when the total amount for the day is given in one dose. In a patient with myxedema it takes three to ten days for the effect of a single dose of 10 mg. of thyroxine on the basal metabolism to become maximum and from seventy to ninety days for the effect on the basal metabolism to wear off.

FALSE POSITIVE SEROLOGIC REACTIONS FOR SYPHILIS IN CEREBROSPINAL FLUID

To the Editor:—Can malaria cause a false positive spinal fluid Kolmer reaction? A man had a 3 plus blood Kolmer reaction and a negative spinal fluid Kolmer reaction. Two weeks later the patient had a 4 plus blood Kolmer reaction and a negative spinal fluid Kolmer reaction. He was then given malaria for some reason or other and had eleven attacks of chills and fever. Three months after malaria therapy his blood Kolmer reaction was 2 plus and his spinal fluid Kolmer reaction was 1 plus. The Kahn test and the colloidal gold test on the spinal fluid were negative. Would you consider this patient to have incidentally developed central nervous system syphilis after malaria therapy, to have developed central nervous system syphilis because of malaria, or to have a false positive spinal fluid reaction due to malaria?

M.D., Washington.

Answer.—Biologic false positive tests for syphilis in the cerebrospinal fluid, as reported by Scott, Reynolds and Mohr, occur in association with meningeal inflammation (tuberculous meningitis, meningococcic meningitis and lymphocytic choriomeningitis). In these conditions there may be a transfer of reagin from the blood serum through abnormally permeable meninges, but falsely positive tests for syphilis also have been reported in the spinal fluids of patients whose blood serologic tests are negative.

This phenomenon is not known to occur in malaria. Several groups of investigators, including Potter, Bronstein and Gruber, and Robinson and McKinney, have performed routine spinal fluid tests for syphilis in cases of vivax malaria, but in no instance were they able to demonstrate either positive flocculation tests or positive complement fixation tests.

In the patient described in the query there was observed on one occasion only a doubtful spinal fluid Kolmer-Wassermann reaction. It is probable that this unconfirmed finding represents a technical laboratory error or possibly a mistake in secretarial transcription of the report. It may be completely disregarded unless (*a*) the patient has clinical evidence of neurosyphilis (what was the "some reason or other" for which induced malaria was given, since this therapeutic method is rarely employed unless for neurosyphilis?) or (*b*) it is proved that he actually has syphilis of any kind (for which the serologic results reported do not constitute justification). In either of these events, but not otherwise, the spinal fluid examination should be repeated in about six months by a reliable laboratory.

Complement fixation tests on spinal fluid are more satisfactory than any flocculation test. Neither, however, can be correctly interpreted on the basis of reports of "positive," "strongly positive," "1 plus," "3 plus" and so on. The amounts of spinal fluid employed in a quantitative test must be stated. Competent laboratories report positive results in terms of the smallest amount of fluid showing such a result, e. g. positive with 0.2 cc. and larger amounts, doubtful with 0.1 cc., negative with 0.05 cc.

TREATMENT OF FACIAL ANGIOMAS

To the Editor:—I am writing in regard to the two notes (July 6, 1946, p. 873 and Nov. 20, 1946, p. 822) on facial angiomas, the latter protesting against the advice given in the answer to a query. The case of infantile hemangioma with eyelid involvement and ptosis as described in the query must be considerably disfiguring at present and would be in the future, should spontaneous involution fail. For this reason expert attention is indicated. I agree in general with the therapy suggested, although nothing definite can be recommended without seeing the patient. The statement of the second note, that a case such as described "will" involute spontaneously, in my opinion would have sounded better if the word "may" instead of "will" had been used. Absolute statements can seldom be pronounced in medicine. It is common knowledge that the majority of hemangiomas involute spontaneously, which means that "not all" hemangiomas do so, otherwise none would be seen in adults. The number of hemangiomas seen in adults is far from small. In my recent tabulation (Hemangiomas: Should Treatment be Expectant or Active? *Rhode Island M. J.* **29**: 658 [Sept.] 1946) in a group of 347 hemangiomas 54 were in adults. In regard to treatment, it is too easy to dismiss every case of hemangioma with the statement that it will disappear in five years. Each individual case must be properly studied. If suitable for expectant therapy, the hemangioma can be left alone. But hemangiomas located, for instance, on the face, producing considerable disfigurement, in the eventuality that they will not involute spontaneously, at the same time being easily and quickly removed without sequelae, should be treated. Spontaneous involution takes five years. The mental anguish of the parents looking at a disfigured child for five years is to be given consideration. Moreover, supposing even 1 case in a thousand will be disfigurement for life because it was an "exception to the rule," wouldn't it be a heavy responsibility for the physician to have decided to wait?

STREPTOMYCIN FOR URINARY TRACT INFECTIONS

JOHN D ADCOCK, M D.
Ann Arbor, Mich.
and
ROBERT T. PLUMB, M D.
San Diego, Calif.

Streptomycin has been shown to be effective in vitro[1] against various gram-negative bacilli frequently responsible for urinary infections which prove refractory to sulfonamide compounds and penicillin. The purposes of the present communication are (1) to report the results of streptomycin therapy in 11 patients with infections of the urinary tract due to gram-negative bacilli which were sensitive to streptomycin in vitro; (2) to correlate results of therapy with the in vitro sensitivity of the infecting organisms and the concentrations of streptomycin attained in the patients' serum, and (3) to report the acquisition, in vivo, of definite resistance to streptomycin by some of the bacteria present in these patients.

SELECTION OF CASES

In the selection of cases for study, both acute and chronic infections were included. A deliberate attempt was made to select patients in whom a single organism appeared to be responsible for the infection, but in 3 instances the infection was polyvalent. Of the 8 patients with univalent infections an organism of the Aerobacter group was responsible in 5, Pseudomonas aeruginosa in 2 and Escherichia coli in 1 case. Ps. aeruginosa was present in each of the cases having polyvalent infections, in combination with Esch. coli in 1 case, Streptococcus fecalis and Proteus vulgaris in another and with Klebsiella granulomatis in 1 case. Each patient had received sulfonamide compounds or penicillin or both, prior to the use of streptomycin, without demonstrable effect on the objective manifestations of the infection.

MATERIALS AND METHODS OF STUDY

Streptomycin was administered by parenteral injection since it has been shown[2] that it is poorly absorbed when given orally. It was supplied as a dry powder of varying degrees of purity. For intramuscular use it was dissolved in distilled water in concentrations of 0.1 Gm.[3] (100,000 units) per cubic centimeter. For continuous intravenous or subcutaneous infusion 1 Gm. was dissolved in 1 liter of 5 per cent dextrose or isotonic solution of sodium chloride. Details of treatment are included in each case report.

Urine for culture was obtained by catheterization prior to starting streptomycin therapy in each case. Thereafter catheterization was avoided in men by collecting the second glass voided specimens after thorough cleansing of the glans and meatus. Each specimen was immediately centrifuged and the sediment promptly placed on culture mediums. Using this technic an occasional contaminant could easily be identified as such. In patients with indwelling catheters and in the 1 woman in the series all specimens were obtained by catheter. All cultures were incubated aerobically.

In vitro tests of sensitivity to streptomycin were carried out on the organisms isolated before the institution of therapy and in most instances were repeated on the strains which could be recovered following treatment. The organism to be tested was inoculated into a series of tubes containing graded concentrations of streptomycin in 5 cc. of 2 per cent proteose peptone broth (Difco) adjusted to p_H 7. The results were read as the lowest concentration of streptomycin which completely inhibited growth, as judged by the absence of gross turbidity after forty-eight hours of incubation.

Determinations of the concentrations of streptomycin in serum and in urine were made by a modification[2] of the method described by Stebbins and Robinson.[4] The serum specimens which were obtained during therapy were taken at times judged to represent the maximum and minimum concentrations for the particular dosage schedule employed.

From the departments of internal medicine and surgery, University Hospital, University of Michigan

These studies were aided by grants from the Executive Committee and from the Board of Governors of the Horace H. Rackham School for Graduate Study of the University of Michigan

The authors are indebted to Dr. Reed M Nesbit for the opportunity to study many of these cases. Cases 7 and 11 were studied through the cooperation of Dr. Rigdon K Ratliff.

The streptomycin sulfate used in case 5 was supplied by the Chas Pfizer & Company, Inc, Brooklyn The streptomycin hydrochloride used in all other cases was supplied by Merck & Co, Inc, Rahway, N J.

Technical help was given by Miss Minnie May Soo-Hoo, Miss Dorothy Artis and Miss Viola Connor

REPORT OF CASES

CASE 1.—I. B., a boy aged 15, was admitted on Jan. 8, 1945, complaining of fever and malaise. His temperature was 103 F. His urine was cloudy with leukocytes; a few red blood cells were present, and stains of the sediment showed gram-positive bacilli. Intravenous pyelograms were normal. His temperature gradually subsided to normal and on January 28 cystoscopy revealed a papillomatous mass in the bladder. Biopsy of this mass was suggestive of rhabdomyosarcoma. On this evidence a partial cystectomy was done on March 2 with removal of a thickened granulomatous area of the bladder. This specimen revealed only severe chronic cystitis without neoplasm.

He was discharged on March 15 but returned in two weeks complaining of chills and fever. His urine was still purulent. During the next three weeks he had four bouts of fever which were not influenced by the administration of sulfadiazine, 6 Gm. per day, or of penicillin, 160,000 units per day. The urine on two occasions revealed a pure culture of Aerobacter aerogenes which was completely inhibited in vitro by 0.8 microgram of streptomycin but not by 0.4 microgram.

On April 24 the administration of streptomycin was started, 1 Gm. per day being given by intravenous infusion for five days. On the fifth day a rash resembling erythema nodosum appeared and promptly subsided when streptomycin therapy was discontinued. After twenty-four hours of therapy the urine showed only an occasional leukocyte. It was sterile when cultured two days and six days, respectively, after the discontinuance of streptomycin. The patient was seen three months later and stated that he had been perfectly well. His urine was normal, and cystoscopy showed a well healed scar in the bladder.

CASE 2.—C. J., a man aged 47, was first seen in May 1944 complaining of headaches and pain in the right flank. His blood pressure was elevated, and intravenous pyelography showed hydronephrosis and hydroureter on the right. Cystoscopy demonstrated a ureterocele on the right which was destroyed by fulguration in August 1944. One week later he was readmitted complaining of chills, pain in the right flank and burning on urination. His temperature was 102 F. There was decided tenderness in the region of the right kidney. His urine was grossly purulent, and stains of the sediment showed gram-negative bacilli. The pain and fever subsided coincident with the administration of sulfadiazine, but the urinary findings remained unchanged. During the succeeding nine months he had innumerable similar episodes. His urine was constantly loaded with pus and bacilli. Several courses of sulfadiazine were without effect on the clinical course or urinary findings. He was readmitted on May 22, 1945 and was given a ten day trial of penicillin, 320,000 units per day, combined with sulfadiazine, 2 Gm. per day, without change in the urine. Each of two urine cultures revealed A. aerogenes which was completely inhibited in vitro by 1.5 micrograms of streptomycin but not by 1 microgram.

On June 8 the intramuscular administration of streptomycin was started, 0.25 Gm. being given every three hours for nine days, a total of 18 Gm. Concentrations of streptomycin in the serum varied from 14 to 25 micrograms per cubic centimeter and in the urine from 700 to 1,600 micrograms per cubic centimeter. Within three days the urine showed only a rare leukocyte and stains revealed no organisms. Urine cultures taken three days after the discontinuation of streptomycin were sterile.

The patient was seen four months later and stated that he had been perfectly well. His urine was normal and was sterile on culture.

CASE 3.—E. T., a man aged 78, had a perineal prostatectomy in 1939. In August 1944 obstructive symptoms returned and a transurethral resection was performed. He was again admitted on Oct. 29, 1945 stating that moderate dysuria and gross pyuria with "clots" had been present for one year. He stated that sulfonamide drugs had never given relief and he had been in another hospital for a ten day period, four weeks previously; while there he had been given both penicillin and sulfadiazine without any change in status. On admission his urine was purulent and repeatedly gave a pure culture of A. aerogenes which was completely inhibited in vitro by 1 microgram of streptomycin but not by 0.8 microgram. Cystometric studies demonstrated an atonic bladder with 200 cc. of residual urine. On November 12 intramuscular streptomycin was started, 0.1 Gm. being given every three hours for five days, a total of 4 Gm. Concentrations of streptomycin in the serum varied from 8 to 11 micrograms per cubic centimeter and in urine from 220 to 320 micrograms per cubic centimeter. Three days after initiating therapy his urine showed only an occasional leukocyte and was sterile, as was a specimen taken six days after the discontinuation of streptomycin. He returned two months later stating that he had been free of urinary symptoms. Routine urinalysis was negative and culture of the urine showed no growth.

CASE 4.—J. W., a man aged 31, diabetic since the age of 12, was first seen in April 1944 with severe diabetic neuropathy requiring amputation on the right foot. Cystometric studies revealed an atonic bladder with 1,200 cc. of residual urine, which was infected. During the next year his diabetes was carefully controlled with improvement in the neuropathy and a return of normal bladder function.

In October 1945 there developed severe dysuria and pyuria which persisted unchanged through several courses of sulfadiazine and one course of mandelic acid. In November and December the urine yielded A. aerogenes on culture. The patient was readmitted on Jan. 5, 1946. His urine was grossly purulent and gave a pure culture of A. aerogenes which was completely inhibited in vitro by 0.8 microgram of streptomycin but not by 0.4 microgram.

Streptomycin therapy was started on January 8, being given by continuous subcutaneous infusion at the rate of 1 Gm. per day. It was discontinued because of an elevation of temperature to 102 F. after a total of 2.5 Gm. of the drug had been given. Concentrations of streptomycin in serum ranged from 10 to 14 micrograms per cubic centimeter and in urine from 190 to 160 micrograms per cubic centimeter. The urine gave a positive culture twenty-four hours after starting therapy but thereafter was sterile and showed only an occasional leukocyte. One month later the patient stated that he had been free of urinary symptoms. Urinalysis was negative, and cultures of urine were sterile.

CASE 5.—F. R., a man aged 44, had been followed since 1931 when his difficulties with renal calculi began. Pyelolithotomy had been performed on the right side in 1933, in 1937 and again in March 1945. A large calculus was removed from the left renal pelvis in May 1945. During this time he was seen repeatedly, and his urine was always purulent. Sulfonamide compounds and penicillin had been given without altering the urinary findings. The urine was first cultured in June 1945 and showed Aerobacter cloacae and a few colonies of Staphylococcus aureus. Cultures made Jan. 9 and Jan. 13, 1946 yielded only A. cloacae which was completely inhibited in vitro by 0.8 microgram of streptomycin but not by 0.4 microgram. Pyelography showed some distortion of the calices but no stones.

On January 15 streptomycin was started, 0.4 Gm. being given every four hours for four days, a total of 9.6 Gm. Concentrations of streptomycin in serum ranged from 26 to 48 micrograms per cubic centimeter and in urine from 800 to 900 micrograms per cubic centimeter. Cultures of urine remained positive for forty-eight hours but were negative thereafter. His urine promptly became grossly clear, but the sediment continued to show numerous leukocytes. Cultures of urine were sterile ten days after the discontinuation of streptomycin but one month later showed Staph. aureus.

The organisms responsible for the infection in the above 5 patients (A. aerogenes in cases 1 through 4 and A. cloacae in case 5) were quite sensitive to streptomycin as judged by in vitro testing. In each case, the concentration of streptomycin in the serum was found to be, or could be inferred to be, approximated ten or more times that required for inhibition of the infecting organism in vitro. After streptomycin therapy there was prompt relief of symptoms, and pyuria disappeared. Urine cultures were sterile within forty-eight hours and remained free of these organisms thereafter.

CASE 6.—W. C., a boy aged 2, began to have pain on urination in March 1945. A greatly distended bladder was found and a suprapubic cystostomy was performed in another hospital. He was transferred to the University Hospital on May 22. On admission there was a suprapubic opening into the bladder. His urine yielded Esch. coli on culture, and he was started on sulfadiazine, 1 Gm. per day. Intravenous pyelograms showed no function on the right and hydronephrosis with hydroureter on the left. On May 28 an endoscopic examination revealed congenital urethral valves, which were destroyed by fulguration. Subsequent to this procedure penicillin, 80,000 units per day, was started and the administration of sulfadiazine was continued. Despite the combined medication the patient began to run a septic fever, and urine cultures taken on June 24 yielded only Ps. aeruginosa which was completely inhibited in vitro by 20 micrograms of streptomycin but not by 16 micrograms. It is probable that Esch. coli was also present but was completely overshadowed by the other organism. All medication was discontinued on June 24.

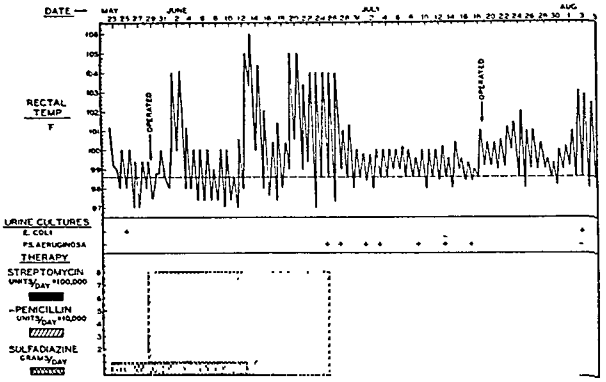

Chart 1 (case 6).—Effect of streptomycin in a patient with acute pyelonephritis due to Ps. aeruginosa and Esch. coli.

On June 26 streptomycin was started, 50 milligrams being given intramuscularly every three hours. After thirty-six hours the dosage was increased to 0.1 Gm. every three hours for eight days, after which it was reduced to the original level. A total of 16.6 Gm. of the drug was given over a period of thirty-seven days. Concentrations of streptomycin in the serum ranged from 6 to 32 micrograms per cubic centimeter and in urine from 160 to 250 micrograms per cubic centimeter.

Chart 1 illustrates the clinical course of this patient. The rectal temperature promptly declined to normal and the pyuria diminished. Cultures of the urine, however, continued to reveal Ps. aeruginosa until the functionless right kidney was removed on July 20, following which Esch. coli reappeared in cultures. The latter organism was not inhibited in vitro by 200 micrograms of streptomycin, and for this reason therapy was discontinued on August 2. During the time that streptomycin was being administered, however, the suprapubic tube was removed, the cystostomy opening healed and the child began to void normally, with 50 cc. of residual urine. After the discontinuation of streptomycin he was given mandelic acid, 12 Gm. daily for twelve days, and was discharged on September 3 with a sterile urine. He was seen three months later with a recurrence of the infection due to a staphylococcus.

CASE 7.—G. T., a man aged 67, had a transurethral prostatectomy on Oct. 10, 1945. Four days later, following a chill, his temperature rose to 104 F. He was given sulfadiazine, at first in dosages of 2 Gm. per day and later in dosages raised to 5 Gm. per day, and 160,000 units of penicillin per day. There was some initial improvement, but the chills and fever reappeared despite continued medication and decided tenderness developed in the region of the left kidney. The urine was grossly purulent, and the leukocyte count rose to 24,000. Urine cultures on October 28 gave a pure culture of Ps. aeruginosa which was completely inhibited in vitro by 16 micrograms of streptomycin but not by 12 micrograms. Administration of penicillin and sulfadiazine was discontinued October 29.

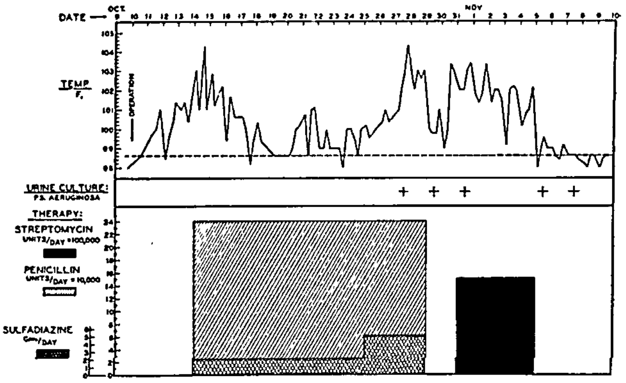

Chart 2 (case 7).—Effect of streptomycin in a patient with acute pyelonephritis due to Ps. aeruginosa.

Streptomycin therapy was started November 1, the drug being given by continuous subcutaneous infusion at the rate of 1.5 Gm. per day for four days. Concentrations of streptomycin in the serum varied from 8 to 17 micrograms per cubic centimeter and in urine from 120 to 230 micrograms per cubic centimeter. Chart 2 illustrates the clinical course of this patient. The pyuria and the tenderness of the flank disappeared promptly, and the leukocyte count dropped to 13,000 although the temperature remained elevated until streptomycin was discontinued. Urine cultures, however, remained positive throughout the period of observation. The patient was again seen in January 1946, at which time he stated that he had been entirely well and his urine had remained clear. Routine urinalysis was then negative, but Ps. aeruginosa was recovered on culture. The in vitro sensitivity of this strain was identical with that of the strain originally isolated.

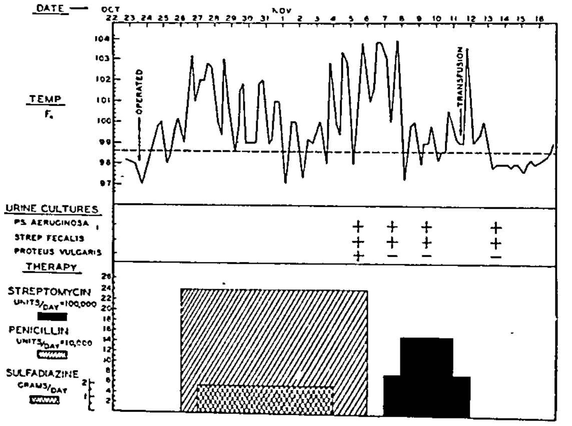

Chart 3 (case 8).—Effect of streptomycin in a patient with acute pyelonephritis due to Ps. aeruginosa, P. vulgaris and Strep. fecalis.

CASE 8.—K. S., a man aged 73, had a transurethral prostatic resection on Oct. 3, 1945. Three days later he had a severe chill and his temperature rose to 104 F. During the next ten days his condition remained essentially unchanged despite the administration of penicillin, 320,000 units per day, and sulfadiazine, 2 Gm. per day. On November 4 he was lethargic and there was well defined costovertebral angle tenderness bilaterally. Cultures of the urine at this time yielded Ps. aeruginosa, P. vulgaris and Strep. fecalis. When tested in vitro the Pseudomonas strain was completely inhibited by 4 micrograms of streptomycin but not by 2 micrograms, the Proteus was inhibited by 0.8 microgram but not by 0.4 microgram, while the Streptococcus required 20 micrograms for inhibition but grew in 16 micrograms. All medication was stopped on November 5, but drainage by indwelling catheter was maintained.

Streptomycin was started on November 7, being given by continuous intravenous infusion at the rate of 1.5 Gm. per day. After twenty-four hours thrombophlebitis developed in the recipient vein, and thereafter the same daily dose was given by subcutaneous infusion. Treatment was continued for four days, the total dose being 6 Gm. Concentrations of streptomycin in serum varied from 13 to 26 micrograms per cubic centimeter and in urine from 560 to 660 micrograms per cubic centimeter. The temperature promptly declined to a maximum of 100 F., except for one rise which followed the transfusion of blood. Chart 3 illustrates the clinical course of this patient. Urine cultures obtained during and following therapy showed that the Ps. aeruginosa and Strep. fecalis were still present. In vitro studies of sensitivity to streptomycin were carried out on the organisms isolated the day after therapy was discontinued. These organisms, presumably descendants of the original strains, were now decidedly resistant to streptomycin, the Ps. aeruginosa requiring 200 micrograms for inhibition, while the Strep. fecalis was not inhibited by 1 mg.

The patient was discharged on November 21 with 450 cc. of residual urine which was purulent. It has not been possible to follow him but from correspondence it has been learned that he suffered a relapse on leaving the hospital and was having intermittent chills and fever, unrelieved by the use of penicillin or sulfonamide compounds.

The last 3 patients (cases 6, 7 and 8) were suffering from acute episodes of pyelonephritis and obtained little or no relief from the administration of sulfonamide compounds and penicillin. Ps. aeruginosa was present in all 3 cases. It was apparently entirely responsible for the infection in case 7, while other bacteria probably contributed to the illness in cases 6 and 8. The strains of Ps. aeruginosa present in these cases were fairly resistant, and the concentration of streptomycin in serum rarely exceeded by any considerable margin the concentration required for inhibition in vitro. Streptomycin appeared to be of considerable value in controlling the more acute manifestations of the infections, but relapse occurred in cases 6 and 8. Cultures of urine obtained after the discontinuation of streptomycin therapy consistently yielded Ps. aeruginosa in all 3 cases.

Case 9.—J. H., a man aged 31, was first seen in May 1945 complaining of severe urgency, frequency and dysuria. His urine was purulent, and cultures showed Ps. aeruginosa. Cystoscopic examination demonstrated slight contraction of the vesicle neck. Retrograde pyelograms were normal. During the next three months he was given sulfadiazine, sulfacetimide, mandelic acid and penicillin at various times without changing the purulent character of his urine and with only temporary relief of symptoms. A culture of his urine on August 3 again yielded Ps. aeruginosa which was completely inhibited in vitro by 20 micrograms of streptomycin but not by 16 micrograms.

On August 6 streptomycin therapy was started, 0.125 Gm. being given intramuscularly every three hours for three days, a total of 3 Gm. It was discontinued following the appearance of a maculopapular rash. Concentrations of streptomycin in the serum ranged from 7 to 10 micrograms per cubic centimeter and in the urine from 220 to 500 micrograms per cubic centimeter. Urine cultures were positive at twenty-four and forty-eight hours after the start of therapy but were negative at the time streptomycin was discontinued. Cultures were again positive twenty-four hours after discontinuing administration of the drug. Pyuria diminished during therapy but promptly reappeared when streptomycin was discontinued. The patient was seen five months later, at which time Ps. aeruginosa was again isolated from the urine. The sensitivity of this strain was identical to that of the strain first tested.

In this case of chronic infection of the lower part of the urinary tract due to Ps. aeruginosa, there was temporary suppression of the infection during treatment with prompt relapse after streptomycin therapy was discontinued.

Case 10.—E. J., a man aged 47, had a history of renal colic dating to 1934. At that time bilateral renal calculi were surgically removed. He had been followed in this hospital since 1938, with several admissions during which he passed calculi. In 1942 a left pyelolithotomy was performed. During all this time his urine was grossly purulent.

He was last admitted on Aug. 4, 1945 complaining of pain in the flank, chills and fever. Intravenous pyelography showed a staghorn calculus on the right with slight distortion of the calices on the left. A right pyelolithotomy was performed August 9, and convalescence was uneventful. His urine remained purulent, however, and did not change with the administration of penicillin, 160,000 units per day. Repeated urine cultures showed the presence of Ps. aeruginosa and K. granulomatis. The former was completely inhibited in vitro by 30 micrograms of streptomycin but grew in 20 micrograms. The latter organism was inhibited by 0.4 microgram but grew in 0.2 microgram.

Streptomycin was started on August 27, being given by continuous intravenous infusion at the rate of 2 Gm. per day. It was discontinued after a total of 4 Gm. had been given because of a rise in temperature to 102 F. associated with generalized aching. The concentration of streptomycin in serum was found to be 38 micrograms per cubic centimeter in the single specimen which was obtained. Concentrations of streptomycin in the urine were not determined. After the discontinuation of streptomycin therapy routine urinalysis was negative, but Ps. aeruginosa was isolated by culture. The patient was last seen on Jan. 26, 1946 when routine urinalysis was again negative. Ps. aeruginosa was, however, again obtained from urine cultures. The in vitro sensitivity of this strain was identical to that of the strain originally isolated.

In this patient it was difficult to be certain which of the two organisms was mainly responsible for maintaining the pyuria. The K. granulomatis, which was relatively sensitive in vitro, disappeared, while the more resistant organism, Ps. aeruginosa, remained without producing symptoms. The concentration of streptomycin in the serum was many times that required for in vitro inhibition of the Klebsiella strain but barely exceeded the in vitro sensitivity of the Pseudomonas.

Case 11.—E. B., a woman aged 70, had complained of mild dysuria and frequency for four years. During this time the urinary sediment showed many leukocytes and bacilli. She had at various times been given azosulfamide (Neoprontosil), mandelic acid, sulfathiazole, sulfadiazine and sulfamerazine with temporary relief. In November 1945 all medication was discontinued and two urine cultures showed only Esch. coli. This organism was completely inhibited in vitro by 1.0 microgram of streptomycin but grew in 0.8 microgram.

On November 27 the administration of streptomycin was started, 0.1 Gm. being given intramuscularly every three hours for five days, a total of 4 Gm. Concentrations of streptomycin in serum varied from 7 to 12 micrograms per cubic centimeter and in urine from 270 to 300 micrograms per cubic centimeter. Daily cultures of the urine were positive throughout treatment. A culture taken two days after the discontinuation of streptomycin therapy became contaminated in handling and in vitro studies were not made. A culture obtained two weeks later again showed Esch. coli, and this strain grew in 1 mg. of streptomycin. During therapy the patient experienced slight relief of symptoms.

In this patient bacilluria persisted despite the fact that the concentration of streptomycin in the serum was several times the in vitro sensitivity of the infecting organism.

COMMENT

Results of Therapy.—The results of streptomycin therapy were most impressive in the 5 patients with chronic infections due to organisms of the Aerobacter group. Coincident with the administration of streptomycin there was prompt relief of symptoms, pyuria disappeared and urine cultures became sterile. These effects persisted after streptomycin was discontinued, attesting to actual termination of the infection rather than a temporary suppressive effect.

The 5 cases in which Ps. aeruginosa was present, alone or in combination with other organisms, responded less satisfactorily. In each case pyuria diminished or disappeared, and there was a rapid decline in temperature in those cases with acute episodes. Ps. aeruginosa was, however, constantly present in urine cultures following therapy. In case 6 this organism disappeared during therapy, but its disappearance followed nephrectomy and was probably not due to the use of streptomycin.

Summary of Results of Streptomycin Therapy

Case	Bacteria Present Before Streptomycin Therapy	In Vitro: *Streptomycin* Required for Inhibition, Micrograms per Cc	Concentration of *Streptomycin* in Serum, Micrograms per Cc		Bacteria Present After Treatment	In Vitro: *Streptomycin* Required for Inhibition, Micrograms per Cc	Total Dose, Gm	Duration, Days	Routes *

† This organism disappeared from the urine following nephrectomy. It is doubtful that streptomycin was responsible for its disappearance

One case of chronic cystitis due to Esch. coli was treated with streptomycin with temporary relief of symptoms and some diminution of pyuria, but the bacilluria persisted. Most infections of the urinary tract due to Esch. coli respond satisfactorily to sulfonamide drugs and for this reason only 1 such case was included in this series.

In most instances a bactericidal effect was obtained when the concentration of streptomycin which was maintained in the serum was approximately ten or more times as great as that required for inhibition of the infecting organism in vitro (see the accompanying table). The effect appeared to be merely bacteriostatic against the more resistant organisms, however, in cases in which the sensitivity of the infecting organism more nearly approached the concentrations attained in serum. The demonstration[2] that the concentration of streptomycin in various tissues is far below that found in the serum may help to explain these relationships. It is probable that additional factors, as yet unknown, are important in determining the outcome of therapy. Although streptomycin appears in the urine in high concentration, it is doubtful that this is of importance in therapy since, in an established infection, there must certainly be invasion of tissue as well as infection of the urine itself.

It should be emphasized that dosage was often determined by the supply of streptomycin which was available and, in many instances, was probably inadequate both in the amount given daily and in the duration of treatment. A much larger dosage is feasible and might be expected to give better results in those infections due to bacteria which are naturally somewhat resistant to streptomycin. So far as comparison is possible, the result obtained in these cases are in general agreement with those previously reported.[5]

Development of Resistance to Streptomycin.—The fact that bacteria may develop increased resistance or tolerance to various chemotherapeutic substances is now widely recognized and is assuming increasing importance in the treatment of infections. It would appear from the experiments of Miller and Bohnhoff[6] that streptomycin is unusually vulnerable in this respect. These in vitro experiments demonstrated that gonococci and meningococci, originally inhibited by concentrations of streptomycin below 40 micrograms per cubic centimeter, readily acquired sufficient tolerance (within six days) to allow them to grow on mediums containing 75 mg. per cubic centimeter. That bacteria may develop increased resistance to streptomycin in vivo has been demonstrated by Buggs, Bronstein, Hirshfeld and Pilling.[1]

Among the bacteria which were isolated following therapy in the cases here reported, there were three organisms that apparently acquired an increased tolerance to streptomycin (see the accompanying table). In case 8 the strain of Ps. aeruginosa which was recovered just prior to therapy was inhibited in vitro by 4 micrograms of streptomycin, while the strain isolated after four days of treatment required 200 micrograms for inhibition. In this same patient the strain of Strep. fecalis which was initially present was inhibited by 20 micrograms but after four days' exposure to streptomycin it grew well in 1 mg. Similarly, a strain of Esch. coli isolated after five days of treatment from case 11 was able to grow in 1 mg. of streptomycin whereas the pretreatment strain was sensitive to 1 microgram. A fourth organism, the Esch. coli isolated from case 6 at the end of treatment, was not inhibited by 200 micrograms of streptomycin. It is probable that this also represents acquired resistance, although the original sensitivity is unknown. These organisms, though their maximum tolerance to streptomycin was not determined, were certainly totally resistant from the clinical point of view.

Unfortunately, the in vitro sensitivity of the strains of Ps. aeruginosa which persisted following therapy in 3 patients was not tested until several weeks or months had elapsed. In each case the sensitivity was identical with that of the original strain. It is impossible to state, however, that the sensitivity was not altered by the exposure incident to therapy.

The clinical implications of this phenomenon seem clear. Should it prove to be of frequent occurrence, the size of the initial dosage of streptomycin will be of extreme importance, and if a bactericidal effect is to be obtained it must be obtained promptly. It is apparent that many problems remain, particularly in regard to the relationship of dosage to the type of infecting organisms.

Toxicity.—Generalized reactions consisting of fever and arthralgias occasionally accompanied by various types of rashes were encountered in patients who received certain rather crude lots of streptomycin. These same lots were productive of irritation at the site of injection and in 1 case led to the development of thrombophlebitis. The more purified preparations, however, gave no evidence of toxicity over the short interval of their use in these patients.

SUMMARY

Streptomycin has been used in the treatment of 11 patients with urinary tract infections due to gram-negative bacilli which had failed to respond to treatment with sulfonamide compounds or penicillin or a combination of the two.

The 5 patients with infections due to organisms of the Aerobacter group obtained prompt relief of symptoms, pyuria disappeared and the urine became and remained sterile. These organisms were extremely sensitive to streptomycin in vitro.

The 5 patients in whom Pseudomonas aeruginosa was present alone or in combination with other bacteria experienced relief of symptoms, and pyuria diminished or disappeared. These effects were often temporary, and bacilluria persisted in each case. These organisms were fairly resistant to streptomycin in vitro.

In several instances the strains of bacteria which were isolated after therapy were much more resistant to streptomycin in vitro than were the strains (presumably the same) which had originally been recovered.

Streptomycin promises to be a useful adjunct to other chemotherapeutic agents in the treatment of certain resistant infections involving the urinary tract.

PRESENT CONCEPTS OF TREATMENT OF INFECTIONS OF THE URINARY TRACT

THOMAS L. POOL, M.D.
and
EDWARD N. COOK, M.D.
Section on Urology, Mayo Clinic
Rochester, Minn.

Until about fifteen years ago management of infections of the urinary tract was carried out in an empirical fashion. The patient who complained of the usual symptoms of such infections consulted a physician and was given a prescription on the basis of his complaint, and no consideration was given to the type or degree of infection present. Little or no attention was paid to co-existing pathologic conditions. Fortunately, due to the advances that have been made in this field in the past fifteen years, present methods of treatment are much more scientific and results obtained in treatment of these infections are more satisfactory.

The early work of Scholl, Janney, Clark, Helmholz and many others has shown the importance of proper bacteriologic study of the urine. If facilities for making cultures of the urine are not available or their use is not practicable, the use of Gram's stain is of the greatest help and will suffice in most instances. Careful microscopic examinations of the urinary sediment must be carried out. In the male it is essential that a clean second glass specimen of urine be obtained, and in the female a specimen obtained by catheterization is the only satisfactory means of ascertaining the exact nature of the disease. Too often patients who had infections of the urethra and prostate were given long courses of oral treatment with one or another of the therapeutic compounds when pyuria was not present.

A study of the acidity of the urine has been of value from the time of the earliest work in this field. The efficacy of methenamine depends on the liberation of formaldehyde in an acid medium, and today, when the proper urinary p_H can be obtained, this drug is still of considerable value when used alone or in conjunction with mandelic acid. The satisfactory administration of the ketogenic diet results in the liberation of certain organic acids in the urine, and when the urine has a sufficiently low p_H bacteriostasis results. Because of the difficulties encountered in administering the ketogenic diet, the introduction of treatment with mandelic acid was a distinct step forward. Also in order for mandelic acid to exert the desired effect in the urine a certain degree of acidity is necessary. It is impossible to depend on acidification alone to produce bacteriostasis, as the metabolism of the body will not allow the production of a sufficient degree of acidity.

The most important single factor in the successful use of any of the drugs now available for treatment of urinary infections is the presence or absence of complications. Early in the work with the ketogenic diet and later with the newer antibiotic agents as they were developed, it was found that eradication of infection was much simpler and easier to bring about if other pathologic conditions, such as chronic cicatricial inflammatory changes, tumor, stone, obstruction, residual urine or foreign body did not coexist. If any of these complications exist, they must be cared for before the infection can be eradicated.

Read in the Symposium on "The Use of Antibiotics in Urinary Infections" before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

MANDELIC ACID

The discovery of mandelic acid by Rosenheim presented the medical profession with the first specific therapeutic compound for treatment of infections of the urinary tract. In spite of the newer antiseptic drugs which have been developed in the past decade, this older drug has not been outmoded. Its greatest value lies in the fact that when indications for its use are present it may be given and few signs of toxicity will develop if a few important points are kept in mind.

Commercially the drug is manufactured in many forms, and it makes little difference which preparation is used. Early work at the Mayo Clinic led us to believe that a daily dose of 12 Gm. mandelic acid was necessary to render the urine bacteriostatic. However, experience has taught that a dose of 8 Gm. a day is sufficient to obtain a satisfactory concentration of the drug in the urine if the intake of fluid is reduced to 1,500 cc. a day.

For mandelic acid to be successful as a urinary antiseptic, not only is a concentration of 0.5 per cent in the urine necessary but also the p_H of the urine must be 5.5 or lower. In our experience administration of this drug for six to eight days is usually sufficient to eradicate the infection if it is amenable to this treatment. The continued administration of the drug for a longer period is attended with little benefit, and we consider it better to stop administration and give a second course in ten to fourteen days.

If the patient has normal renal function, the drug is relatively innocuous. Some patients complain of nausea and vomiting after they have taken mandelic acid, but this evidence of toxicity can be kept at a minimum if the dosage is reduced for the first twenty-four hours. If patients have disturbed renal function, mandelic acid is definitely irritating to the kidneys and may cause secondary increase in the concentration of blood urea. In our opinion if the level of the blood urea is 50 mg. or more per hundred cubic centimeters administration of the drug is contraindicated. In the older age groups this drug is definitely not well tolerated, and if its use is necessary it should be given with care.

The efficacious use of mandelic acid is confined to those cases in which infection is caused by gram-negative bacilli or Streptococcus fecalis. In those cases in which other streptococci or staphylococci are responsible for the disease the drug is of little value.

SULFONAMIDE COMPOUNDS

The introduction of the sulfonamide compounds approximately ten years ago was another step forward in the management of infections of the urinary tract. Today many varied forms are obtainable for clinical use. In our experience sulfathiazole and sulfacetimide are as satisfactory as any of the other forms in treatment of urinary tract infections although all the other forms of the sulfonamide drugs are used frequently with good results and should be tried in those cases in which the patient does not tolerate any one particular form. We feel that administration of the sulfonamide compounds in doses of more than 30 to 40 grains (2 to 2.6 Gm.) a day is seldom indicated in combating infections of the urinary tract. Doses greater than this, we believe, do not offer anything further in the management of these cases. If the daily dose is kept at 30 to 40 grains (2 to 2.6 Gm.) and the intake of fluid is at least 2,000 to 2,500 cc. a day, renal complications are infrequently encountered.

A good general rule to bear in mind is: always observe the patient closely. When any patient is given the drug he should be seen by a physician within twenty-four hours and checked for any signs of toxic reactions. If cyanosis, nausea and vomiting, fever or cutaneous reactions are present, further administration of the drug should be undertaken with great care. Less important symptoms, such as headache, vertigo, malaise and weakness, do not necessarily require that administration of the drug be stopped but they do indicate that careful observation of the patient should be continued.

Usually reduced renal function is not a contraindication to use of the sulfonamide drugs, and it is not necessary, with the low dosage required in treatment of infections of the urinary tract, to submit patients to detailed and frequent blood studies while they are undergoing treatment. A limited number of patients have an idiosyncrasy to these drugs, and this can be discerned early if a close clinical check is kept on the patient in the first twenty-four hours that he takes the drug.

The sulfonamide compounds usually are considered to be effective against most of the gram-negative organisms infecting the urinary tract and most of the gram-positive cocci, with the exception of Str. faecalis.

ARSENICAL COMPOUNDS

The intravenous use of arsenical compounds has long been known to be of value in combating coccal infections of the urinary tract as well as certain bizarre infections, such as so-called amicrobic pyuria. The dose required is less than that given to combat syphilis. In former years neoarsphenamine was usually used in combating the coccal infections of the urinary tract, but more recently many observers have reported equally as good results and fewer toxic reactions with oxophenarsine hydrochloride. The dose of oxophenarsine hydrochloride is 0.03 to 0.04 Gm. given intravenously. This dose is given every four or five days until three doses have been administered. If any disturbance of renal function is present, it is well to consider some form of treatment other than administration of the arsenical drugs.

PENICILLIN

Penicillin was heralded as a cure for almost all infections. It has been given a fairly complete clinical trial, and we find it has not proved to be of great value in combating the usual nonspecific infections of the urinary tract. The excellent results with this drug in treatment of gonorrheal infections are well known. In certain cases of staphylococcic infections and perhaps of some infections caused by Str. faecalis penicillin has clinical value, especially when large doses are used. However, in the usual cases of infections of the urinary tract in which gram-negative bacilli are the causative organisms this drug is of questionable value. The varied results obtained in these cases suggest the possibility of a variation of the sensitivity of various strains of gram-negative bacilli to penicillin.

Because of the general public interest and demand, a small series of patients who had interstitial cystitis were treated with a thorough course of penicillin at the Mayo Clinic. All the patients thought at first that they received benefit, but this benefit was of short duration. None of these patients received permanent relief of symptoms.

An uncommon complication following transurethral manipulation for diagnosis of stone, litholapaxy or prostatic resection is periurethral inflammation. In a few cases in which this inflammation has progressed and abscesses have formed, intramuscular administration of penicillin has proved to be of the greatest value. It might be said that the results have been almost spectacular, for within twenty-four hours after the patient has received the first dose of penicillin periurethral inflammation has diminished rapidly. This has seemed to be true particularly when penicillin has been given intramuscularly in conjunction with oral administration of one of the sulfonamide drugs.

The synergistic action of penicillin with other therapeutic agents has not been tested adequately as yet, and further clinical investigation will be necessary for proper evaluation of this possible action.

STREPTOMYCIN

The stimulus provided by the discovery of some effective bactericidal agents has increased the amount of investigative work that has been done in the past few years. Penicillin, actinomycin and gramicidin have proved to be effective against gram-positive organisms but have had little effect on the gram-negative organisms. In the search for a substance which would be bactericidal in its effect on organisms of all types, Schatz, Bugie and Waksman in 1944 described the isolation of a new antibacterial substance, streptomycin, from the culture filtrate of Actinomyces griseus. They found that this antibiotic had relatively low toxicity and that it exerted a definite antibacterial action against most gram-positive and gram-negative organisms.

Streptomycin must be given parenterally because when it is given orally practically none of it is absorbed from the gastrointestinal tract. After one parenteral injection a high percentage of the drug is excreted in the urine within twelve hours. It produces few if any signs of toxicity, and to the present time in our experience it has caused no impairment of renal function, no damage to the hematopoietic system, no febrile reactions and no cutaneous eruptions. A few patients have noted headache, a peculiar taste in the mouth, flushing of the face and nausea after injection, but these symptoms have been of short duration. In a few cases tinnitus and vertigo have been noted and in 1 or 2 of these cases after a long period of administration of the drug ataxia also developed. Apparently, too, in a few cases signs of vestibular disturbance may develop.

In all our cases the drug was given intramuscularly every three to four hours. The usual dose has been 1 Gm. a day in divided doses. At the present time, however, it is our opinion that the proper dose is at least 3 Gm. a day for the first few days. Since most of the organisms found in the urinary tract will alter their sensitivity to streptomycin when exposed to it for a period of time, we believe that the drug should be given in large doses at the beginning if the desired effect is to be obtained.

With regard to the effects of the drug on the different organisms, we can say that in practically all instances Aerobacter aerogenes and Proteus ammoniae are destroyed rapidly. Staphylococcus aureus and the colon bacillus are eradicated in perhaps 50 per cent of cases. Results of treatment of infections caused by Str. fecalis or Pseudomonas aeruginosa have been uniformly poor. Undoubtedly, too, there is a variation in the way certain strains of the same organisms respond to the drug. In many of our cases infection has recurred after the administration of streptomycin was discontinued.

Streptomycin has not been the panacea that was anticipated, and the same general considerations which apply to the results obtained with other therapeutic agents must be kept in mind.

In collaboration with Hinshaw, Feldman and Pfeutze and with Greene we have used streptomycin in 14 cases of tuberculosis of the urinary tract. In 8 of these definite symptomatic improvement was noted. Vesical symptoms improved, pyuria was decreased and acid-fast organisms were found in stained smears of urine less and less frequently. In 2 cases the disease was arrested; this conclusion was reached because on inoculations of the urine of these patients into guinea pigs tuberculosis did not develop.

SUMMARY

Two important factors must be considered in the management of infections of the urinary tract. The first is the coexistence of other pathologic processes in the urinary tract. It was observed early that the presence of obstruction, tumor, stone or pronounced chronic inflammatory changes in the urinary tract definitely reduced the efficacy of the ketogenic diet in the eradication of urinary infection and that when none of these pathologic processes were present the results of treatment with the ketogenic diet were much better. Exactly the same observations were made when mandelic acid, the sulfonamide compounds, penicillin and streptomycin were used. The other factor is the variation in the results obtained against various strains of organisms. This definitely suggests the importance of using various therapeutic compounds in alternate courses if one or another fails to eradicate the infection. Of course it is useless to do this if coexisting pathologic conditions have not been removed first of all.

For the routine treatment of infections of the urinary tract, mandelic acid and the sulfonamide compounds are still the drugs of choice. Penicillin is a great adjunct to treatment, but it has not been the boon for which we had hoped in the ordinary case of nonspecific infection of the urinary tract. Streptomycin produces spectacular results in some cases of resistant urinary infection but cannot be used routinely at the present time. Our studies concerning this drug are incomplete because the supply has been so limited that it has been impossible to carry out the investigative work that should go along with the study of any antiseptic.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ADCOCK AND PLUMB AND DRS. POOL AND COOK

DR. GILBERT J. THOMAS, Beverly Hills, Calif.: The paper of Drs. Cook and Pool containing data from their vast experience has brought our information up to date concerning the proper use of urinary antiseptics. The use of controls in order to evaluate the results obtained in attempts to rid organs or tissues of the human body of pathogenic bacteria is very important. Dr. Adcock's paper emphasizes the importance of carefully controlled experiments when these substances are administered. There is not at present a single drug, chemotherapeutic agent, antibiotic or method of changing the physical properties of the urine that will completely disinfect the urine. The first effective methods of disinfection of the urine changed its physical properties. Alkalinization was used against infection due to the coccus group and acidification against those due to the bacillary group. The first drug that was effective was Hexamine (methenamine). Its successful action in dealing with infection due to colon bacilli was dependent on changing the physical properties of the urine so that it became acid and the drug was thereby broken up to release formaldehyde. In addition to the liberation of formaldehyde the change in the physical properties of the urine to acid with a p_H of 5.2 or less was a major factor in controlling the continued growth of colon bacilli. Before the advent of antibiotic substances mixed infections had to be controlled by alternating the changes in the physical properties of the urine. It was acidified for ten days and then alkalinized for a like period. Hexylresorcinol in a 1:1,000 solution changed the physical properties of the urine by increasing the surface tension. These changed conditions which had to be prolonged produced a bacteriostatic action in most urines and a bactericidal action in a few. The clinicians reporting today infrequently use the term "cure." There were just 5 cures in Dr. Adcock's carefully controlled group. These occurred in bacterial infections or with types of bacteria that heretofore have been exceedingly resistant to any other method of treatment. I have had the opportunity of seeing 1 or 2 cases of urogenital tuberculosis that Drs. Green and Pool have treated with streptomycin. I have had several cases of tuberculosis but have been unable to obtain sufficient amounts of streptomycin to apply adequate treatment. One of these patients had had streptomycin daily for ninety days, receiving over 2 million units a day. His clinical symptoms were improving, the character of the urine was better and an occasional specimen contained no Mycobacterium tuberculosis. The man's general condition was improved, but he still had some frequency. Dr. Pool can tell us more about the dosage used and the 12 cases they have treated.

DR. JAMES E. POTTER, Palm Springs, Calif.: My experience with the use of penicillin has probably been the same as every other man's who had used much of it. It has been both encouraging and discouraging. I have patients come in and I think, "I can clear you up in just a few days with a few injections of penicillin." I give it, but I am disappointed. I have made the practice of running cultures, but one cannot definitely put one's finger on what organism will respond to penicillin treatment. Trial and error is the only way to find out. I give penicillin to practically every patient with urinary infection that comes into my office, and in most of them I get a very satisfactory response.

I agree with Dr. Adcock thoroughly in that the initial dose of streptomycin and also the initial dose of every other urinary antiseptic should be a maximum dose. We should not temporize. If a drug is indicated, my idea is to use it in full dosage.

DR. JOHN W. HIRSHFELD, Ithaca, N. Y.: I had the opportunty two years ago of taking part in some of the initial clinical studies of streptomycin. Experience in the treatment of surgical infections convinced me that the approach which Dr. Adcock and his co-workers have made is the only logical one. Different strains of the same organism vary enormously in their resistance to streptomycin. Therefore, unless the resistance of the organism is determined before treatment is instituted, one has no knowledge of what constitutes a dose of streptomycin which will be adequate to inhibit its growth. Streptomycin is a vulnerable antibiotic agent in that most bacteria possess the power of developing a tolerance for it rapidly. For these reasons it is foolish to undertake treatment with an inadequate dose. It is important to know before starting that a dose large enough to do the job can be given, because with streptomycin one usually has just one chance. Treatment cannot be started with a small dose and the amount then gradually increased. Although streptomycin is excreted in very high concentrations in the urine, the urinary concentration of the drug is probably not the important consideration. The source of these infections is in the tissue, not in the urine. Maintaining a high concentration in the urine and not in the tissue is like trying to irrigate an infected compound fracture wound with an antiseptic. Every one knows that it doesn't accomplish very much. It is important that streptomycin should be given in concentrations high enough to inhibit the organisms in the tissue and the concentration in the urine should probably be forgotten. None of the antibiotic agents are effective in the presence of foreign bodies, dead tissue and walled-off abscesses. Since the physician has only one chance with streptomycin, it is foolish to start therapy until abnormalities of the urinary tract which will make it subject to reinfection have been corrected surgically.

DR. RAY JONES, Seattle: There is one comment that has been missed entirely in discussion of chemotherapy in the urinary infection, namely, the development of immunity by the patient before chemotherapy is given. If the physician only waits until nature has a chance to establish a little immunity itself, before he begins chemotherapy, then the incidence of improvement will necessarily rise. If one goes into socialized medicine routines and gives everyone the same medicine immediately when the diagnosis is made one will be but practicing on the percentage of cure basis, not scientific medicine. As to the gonococcus being licked, according to the Health Department reports there has been a great increase in gonorrhea in the last six months; it is going up by leaps and bounds. The gonococcus has acquired a tolerance to sulfonamide drugs, now to penicillin, what next? However, physicians are not seeing that gonorrhea. Perhaps that is the reason we think that it is decreasing. It goes to the Health Department, where it can get treatment for nothing. Gonorrhea is completely socialized, so regardless of the financial status of the patient he can go down there and get free treatment. It has become such that we doctors who have been doing venereal disease work are getting discouraged. I am seriously thinking of retiring to the farm and raising skunks, in hopes that the government will keep its nose out of that.

DR. VICTOR LESSPINASSE, Chicago: I had a very satisfactory experience with streptomycin. A man 50 years of age had a ureteral stone which I manipulated. The next morning his temperature was up a little bit. I promptly ordered some penicillin. The following morning his temperature was up more and the third morning it reached 105 F. He was beginning to have some jaundice. The blood count revealed 3½ million red cells, and it had been 5 million in the routine blood check when he came in. The next morning his temperature was 105.5 F. and his red blood cell count was 1½ million. A culture of the urine revealed Bacillus pyocyaneus. I turned him over to Dr. Priest and the streptomycin group; they gave him streptomycin and his temperature dropped just as in Dr. Adcock's case. The fever never came back. Three weeks later his blood count gradually improved under symptomatic treatment; he still had the organisms in his urine, but he was symptom free. His blood had come back to normal. Then three weeks after that his urine culture was negative and his blood count, blood condition and general clinical condition stayed perfectly normal. That, to me, was a beautiful demonstration of the power of streptomycin. Personally, I have had very little experience with B. pyocyaneus. I always thought it was just a saprophyte and had no great pathologic significance, but I find now that at times it is quite a powerful pathogenic organism.

The Conservation of Energy.—In the 1840's Mayer and Helmholtz in Germany, Colding in Denmark and Joule in England independently arrived at the principle of the conservation of energy. The first to formulate this principle, Robert Mayer, was led to his discovery by a biological observation. When serving as a ship's doctor he noticed at the harbor of Surabaya in 1840 that the venous blood of the Javanese was almost as bright red as the arterial blood. This, he assumed, was because a smaller amount of oxidation is required to maintain the body temperature in the tropics than in colder climates. Two years later he announced the law of the conservation of energy, but he had great difficulty in getting his paper published and did not live to see his ideas accepted. The principle of the conservation of energy claims that in all the changes which occur in nature there is something that remains constant, the energy. If energy of one kind disappears an equivalent amount of other forms of energy makes its appearance.—Nielsen, J. Rud: Atomic and Molecular Energies, *Scient. Monthly*, December 1946.

EXUDATIVE TONSILLITIS AND PHARYNGITIS OF UNKNOWN CAUSE

COMMISSION ON ACUTE RESPIRATORY DISEASES
Fort Bragg, N. C.

The assumption is made commonly that the exudative type of tonsillitis and pharyngitis is caused by beta hemolytic streptococci. While this statement is true in many instances, it is by no means universally true. In various studies of respiratory disease, comment has been made on the occurrence of cases of exudative tonsillitis and pharyngitis not due to hemolytic streptococci.[1] Similarly, during three years of observation of soldiers with acute respiratory disease at the Regional Hospital, Fort Bragg, many instances of exudative tonsillitis and pharyngitis were encountered in which beta hemolytic streptococci could not be incriminated as the causative agent. Indeed, in these studies it was demonstrated that about half of all cases of exudative tonsillitis and pharyngitis had neither bacteriologic nor serologic evidence of streptococcic infection.

The clinical characteristics and laboratory findings of streptococcic and nonstreptococcic forms of exudative tonsillitis and pharyngitis and the criteria by which the two conditions may be distinguished have been presented in several previous studies.[2] The purpose of this report is to summarize some of these data and to describe, by illustrative case reports, some of the features of exudative tonsillitis and pharyngitis of unknown cause.

METHODS

The clinical, bacteriologic and serologic methods used in these studies have been described.[2a] The studies were carried out during the spring of 1943, the spring of 1944 and the winter of 1945. Most of the patients were Army recruits hospitalized for respiratory disease. Daily examinations were made of the patients during their hospital stay. Throat cultures were taken on three consecutive days and examined by the usual cultural methods for beta hemolytic streptococci and other aerobic flora. Serologic identification of beta hemolytic streptococci according to group [3] and type [4] was made.[5] Antistreptolysin [6] and antifibrinolysin [7] tests were carried out with acute phase and convalescent phase serums, obtained three to eight weeks after the onset of illness, in all subjects.

RESULTS

A comparison of some clinical features of streptococcic and nonstreptococcic exudative tonsillitis and pharyngitis is shown in charts 1 and 2. These results are based on an analysis of 54 cases of exudative tonsillitis and pharyngitis in which both bacteriologic and serologic observations indicated that the beta hemolytic streptococcus was the causative agent and 125 cases in which similar procedures did not yield evidence of infection with this organism.

Inspection of chart 1 reveals that streptococcic infections of the throat have a more acute onset than do nonstreptococcic infections. Such symptoms as chilliness, feverishness, headache and malaise, which indicate a systemic reaction, are also more common in the former group, but the difference is slight. In contrast, the nonstreptococcic cases tend to involve the lower portions of the respiratory tract more frequently as witnessed by their greater incidence of hoarseness, sputum, cough and pain in the chest. The frequency of pain on swallowing (sore throat) is approximately the same in the two groups. In the aggregate, differences between the clinical pattern of the two types of exudative tonsillitis and pharyngitis are evident. Obviously, however, such differences are of little help in the differential diagnosis of a particular case.

The physical examination yields data more helpful in differential diagnosis. Chart 2 reveals that abnormal physical conditions are considerably more frequent in cases of streptococcic than in those of nonstreptococcic origin. Patients in the streptococcic group give the general appearance of a more severe illness; they frequently exhibit diffuse redness of the mucous membranes of the palate, tonsils and posterior pharygeal wall, and in the majority of them some degree of edema of these tissues is evident. The presence of enlarged and tender lymph nodes is of considerable differential value. All these observations are less common in nonstreptococcic exudative tonsillitis and pharyngitis. Again, however, these are aggregate observations and in individual cases considerable variation from the average has been encountered.

The total and differential leukocyte counts are of real value in diagnosis. The average total leukocyte count in streptococcic tonsillitis and pharyngitis was 13,427, with 79 per cent polymorphonuclear leukocytes, and in the nonstreptococcic cases 9,024, with 67 per cent polymorphonuclear leukocytes.

Although both diseases are of short duration, with fever generally less than four days, the maximum temperature in streptococcic infections tends to be slightly higher than that in nonstreptococcic infections, averaging 102.5 F. in the former and 101.7 F. in the latter.

The extent and appearance of the exudate in the throat is, in general, different for the two varieties of

tonsillitis and pharyngitis. When caused by streptococci, the exudate is usually yellow and large in extent; not infrequently it is confluent in one or more areas. Nonstreptococcic exudate, in contrast, is often white or gray, pinhead size, and is frequently distributed over enlarged follicles of lymphoid tissues on the posterior pharyngeal wall. Although both types of exudate are more commonly found in subjects with large tonsils, the gray, pinhead variety is seen more frequently than the confluent type in subjects who have had a tonsillectomy and exhibit either clean tonsillar fossae or tonsillar tags.

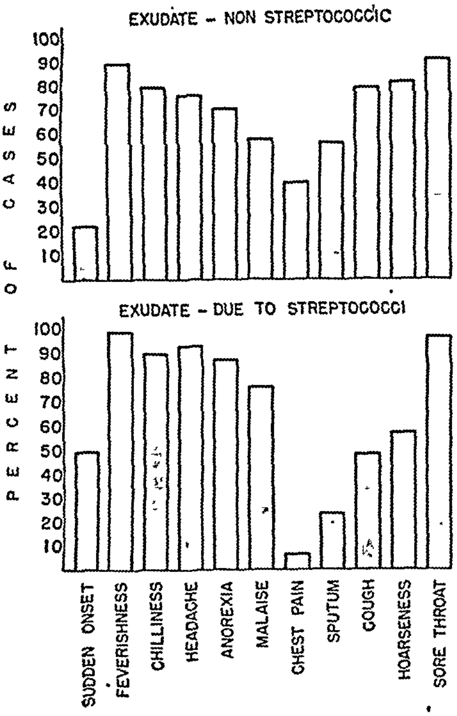

Chart 1.—Frequency of various symptoms in 125 cases of exudative tonsillitis and pharyngitis of nonstreptococcic (unknown) origin (upper half) and 54 cases of exudative tonsillitis and pharyngitis due to beta hemolytic streptococci (lower half).

Streptococcic infections of the throat, therefore, generally have an acute onset with sore throat and systemic symptoms, a short illness with fever which may be high but does not persist for more than four days, diffuse redness and edema of the mucous membranes of the oropharynx, a discrete or confluent exudate, usually on the tonsils, enlarged and tender cervical lymph nodes and a moderate leukocytosis. Nonstreptococcic exudative tonsillitis and pharyngitis is generally a milder disease. The onset is more gradual, and sore throat and constitutional symptoms predominate at onset, but, later, involvement of the lower portions of the respiratory tract develops. Fever also is not often longer than four days in duration, but the height of the fever is lower than in streptococcic cases. Redness and edema of the mucous membranes is less decided and may be absent. The exudate is less extensive, often pinpoint, and is frequently confined to the posterior pharyngeal wall rather than the faucial tonsillar tissue. Cervical lymphadenopathy is not prominent, and the total leukocyte count is either normal or but slightly elevated.

REPORT OF CASES

The following case reports have been selected to illustrate the typical pictures of the nonstreptococcic and streptococcic forms of exudative tonsillitis and pharyngitis and to indicate the variations from the usual which have been encountered. None of the subjects included had clinical or roentgenographic evidence of pulmonary involvement. Unless indicated, specific chemotherapy was not used.

CASE 1.—This patient was studied during two hospital admissions for exudative tonsillitis and pharyngitis. He was admitted for the first time during an explosive epidemic of septic sore throat due to beta hemolytic streptococcus of group A, type 5.[8] During this illness, however, he was found to have nonstreptococcic exudative tonsillitis. Although his illness was mild, there were also a number of proved type 5 streptococcic infections among other members of his organization which, in appearance, were similar to the present case. A month after the initial illness the patient again had exudative tonsillitis and on this occasion had an infection due to the epidemic strain of type 5 streptococcus. The contrast between the data on the two admissions is illustrated in chart 3.

First Admission.—A white soldier aged 18 was hospitalized Nov. 20, 1943 because of sore throat and hoarseness for one day. He had no constitutional symptoms. The admission temperature was 99.6 F., and he appeared only mildly ill. The tonsils were extremely large but only slightly injected, and the oropharyngeal mucosa did not appear edematous. There were scattered discrete spots of white exudate on both tonsils. The anterior cervical lymph nodes were moderately enlarged but only slightly tender.

Without specific medication, he improved rapidly. The exudate disappeared in the course of six days and both the tonsils and the cervical lymph nodes decreased in size. The leukocyte count was slightly elevated on admission but normal thereafter. Nine throat cultures did not yield beta hemolytic streptococci, and streptococcus antibodies did not develop during three weeks of observation.

Second Admission.—The patient was readmitted Dec. 20, 1943 because of headache, dizziness, fever, chilliness and aching in the back for one day. He did not complain of sore throat until the third day of illness. On this admission he appeared acutely ill and had a temperature of 104 F., a flushed face, injected eyes and a rapid pulse rate. The tonsils were enormous, nearly meeting in the midline, and were edematous and diffusely

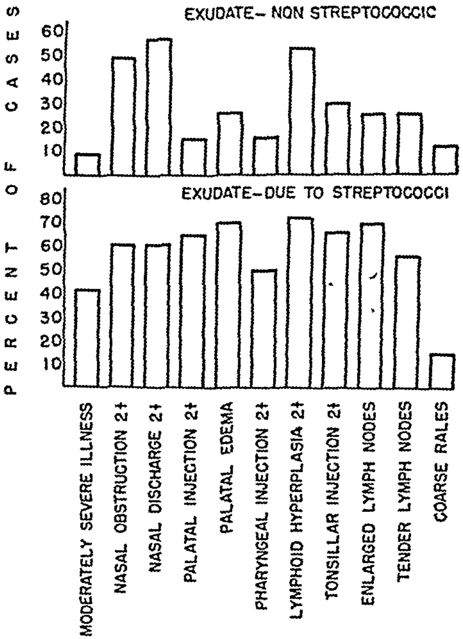

Chart 2.—Frequency of various abnormal physical findings during hospital course. Same groups of cases as in chart 1. The symbol 2+ indicates diffuse or severe involvement.

[8] Commission on Acute Respiratory Diseases: A Study of a Food-Borne Epidemic of Tonsillitis and Pharyngitis Due to β-Hemolytic Streptococcus, Type 5, Bull. Johns Hopkins Hosp. 77: 143-210 (Sept.) 1945.

injected. There were numerous large flat patches of yellow exudate on both tonsils. The uvula was edematous. The anterior cervical lymph nodes were enlarged and tender.

Fever persisted for eight days. Again without specific medication, the tonsils decreased in size and regained their normal color, and the edema of the soft palate disappeared. The exudate cleared from the tonsils over the course of a week. The size of the lymph nodes in the neck decreased, and the tenderness to palpation disappeared. The total leukocyte count was 17,300, with 79 per cent polymorphonuclear leukocytes. A predominant growth of beta hemolytic streptococci of group A, type 5, was recovered repeatedly from throat cultures. During convalescence from this illness streptococcus antibodies (antistreptolysin and *antifibrinolysin) were demonstrated in the patient's blood.*

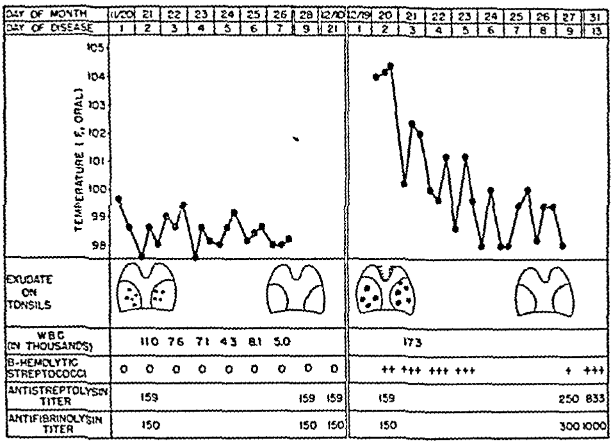

Chart 3. (case 1).—Temperature graphs and clinical and laboratory data on two hospital admissions, the first for nonstreptococcic exudative tonsillitis and the second for exudative tonsillitis due to beta hemolytic streptococci.

In this and the following figures, the appearance of the throat is depicted diagrammatically to indicate the size of the tonsils or tonsillar remnants, the presence of hypertrophied lymphoid follicles, the extent of exudate and the presence and degree of edema of the soft palate. A semiquantitative measure of the number of beta hemolytic streptococci in throat cultures is indicated by plus marks, +++ and ++++ being predominant growths of these organisms on blood agar plates. The titers of antistreptolysin and antifibrinolysin are indicated in units.

This patient was unique in that he experienced a mild illness due to nonstreptococcic exudative tonsillitis followed within a month by a severe attack of streptococcic tonsillitis. The first attack was characterized by little fever, few constitutional symptoms, moderate amounts of exudate with few signs of inflammation of the pharyngeal mucosa and a normal to slightly elevated leukocyte count. The second illness was marked by prostration, high fever, considerable swelling and redness of the tissues of the throat, enlargement and tenderness of the cervical lymph nodes and brisk leukocytosis. In this instance, therefore, clinical differentiation between the two diseases should not have been difficult.

In contrast, the records of 2 patients in whom clinical differentiation could not be made are illustrated in chart 4.

Case 2 (Chart 4, J. M.).—An 18 year old soldier was hospitalized May 8, 1943 because of fever, chilliness, malaise and sore throat which began the preceding evening. He appeared moderately ill, had a flushed face and had a temperature of 102 F. The tonsils had been removed cleanly. On the posterior pharyngeal wall were a number of large lymphoid follicles, which were pink in color but not diffusely injected. Surmounting these follicles were many pinpoint flecks of yellow exudate. The rest of the throat appeared normal. The cervical lymph nodes were not enlarged or tender. In the course of two days, the exudate disappeared and the lymphoid follicles decreased somewhat in size but remained large. Systemic symptoms were present only on the first two days of illness. Soreness of the throat persisted for four days; cough or hoarseness were not present. The leukocyte count was elevated to 17,100, with 79 per cent polymorphonuclear leukocytes. Beta hemolytic streptococci of group A, type 3, were present in predominance in throat cultures, and streptococcus antibodies (antistreptolysin) developed during convalescence.

Case 3 (Chart 4, R. G.).—This 18 year old soldier was admitted to the hospital May 7, 1943 after twenty-four hours of sore throat, feverishness, headache and cough. Although the temperature was 102 F. he appeared only mildly ill. The tonsils had been removed cleanly. On the posterior pharyngeal wall there were a number of large follicles of lymphoid tissue, moderately injected and red, on which were scattered pinpoint spots of yellow exudate. There was also slight edema of the soft palate. The cervical lymph nodes were not enlarged or tender. The exudate disappeared in the course of four days, as did the signs of inflammation and swelling of the tissues of the throat. The fever and systemic symptoms were present for four days, but sore throat and cough persisted for a few more days, and hoarseness developed later in the illness. The leukocyte count was normal. Bacteriologic and serologic studies yielded no evidence of a streptococcic infection.

These 2 patients were hospitalized within a day of each other and were seen by the same examiner, who noted, at the time, the similarity in appearance of the throat in the two cases. Clinically, the only clue to the correct diagnosis was the leukocyte count, which was *elevated in the streptococcic case and normal in the* nonstreptococcic case. In subjects whose tonsils have been removed, hypertrophied islands of lymphoid tissue on the pharyngeal wall are frequently the site of inflammation and exudate in the presence of infections which ordinarily involve the faucial tonsils.

The following 3 case reports (chart 5) illustrate the usual pattern of illness and appearance of the throat in cases of exudative tonsillitis and pharyngitis of unknown cause.

Case 4 (Chart 5, I. Y.).—This soldier noted a sore throat and cough on the evening of March 24, 1944. The next day he felt feverish and chilly, complained of nasal obstruction and aching muscles and lost his appetite. He appeared only mildly ill, although the temperature rose to 103.4 F. on the day of admission. The tonsils had been removed, but small tonsillar tags were present. They were only slightly reddened and contained no exudate. On the posterior pharyngeal wall were a number of large lymphoid follicles which were diffusely red, and on some of them were discrete spots of gray exudate. On the second hospital day the exudate was more extensive but was still

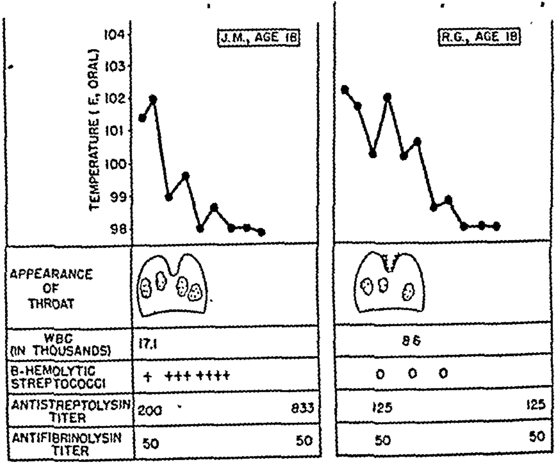

Chart 4.—Comparison of clinical and laboratory features of 2 cases of exudative pharyngitis, one due to beta hemolytic streptococci (case 2, J. M.) and the other of unknown cause (case 3, R. G.).

confined to the summits of the red lymph follicles. The cervical lymph nodes were neither enlarged nor tender. There was moderate nasal obstruction and discharge.

The temperature fell to normal by the fifth day of illness, at which time the signs of inflammation in the throat had also disappeared. However, sore throat and cough persisted for several more days, and, in addition, in the latter part of the illness hoarseness, sputum and thoracic pain associated with coughing were present.

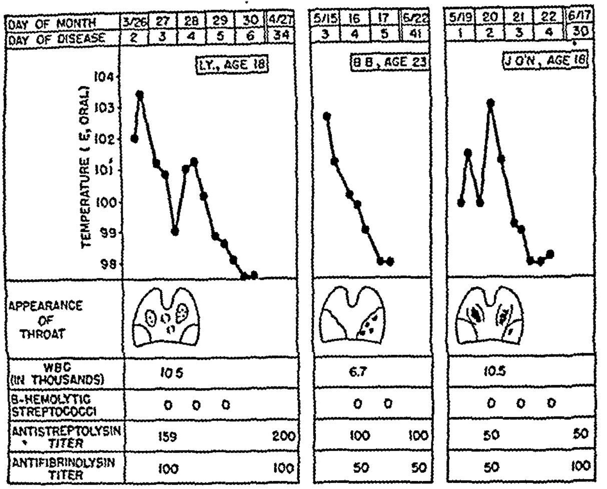

Chart 5.—Clinical and laboratory features in 3 cases of nonstreptococcic exudative tonsillitis and pharyngitis: case 4, I. Y., case 5, B. B., and case 6, J. O'N.

CASE 5 (Chart 5, B. B.).—A 23 year old soldier had a chill on May 13, 1944 followed by fever, headache, loss of appetite and sore throat, which persisted until he was hospitalized two days later. He appeared only mildly ill despite a temperature of 102.6 F. The tonsils, which were of moderate size, were diffusely injected with some evident swelling of the mucosa. There were discrete spots of exudate on the left tonsil. The soft palate appeared normal, and the posterior pharyngeal wall revealed only a few small reddened lymphoid follicles.

The temperature fell rapidly to normal on the second hospital day. The exudate also disappeared rapidly, and the tonsils decreased in size. The cervical lymph nodes were tender to palpation for a day but were not enlarged. Cough, hoarseness, sputum or pleural pain were not present.

CASE 6 (Chart 5, J. O'N.).—This soldier was hospitalized on May 19, 1944 twenty-four hours after the onset of sore throat and cough accompanied with fever, chilliness, headache and nasal stuffiness. He appeared to be mildly ill. The tonsils had been removed but small tags remained; they were only slightly injected and had a small amount of exudate. On the pharyngeal wall, near the posterior tonsillar pillars, were areas of large reddened lymphoid tissue in the form of bands. These were studded with white exudate. The cervical lymph nodes were not palpable or tender.

The temperature rose to 103 F. on the second day but was normal on the third day. The local evidences of inflammation in the throat and the systemic symptoms both disappeared as the temperature returned to normal, but sore throat and cough persisted for a day longer.

Bacteriologic and serologic studies did not yield evidence of hemolytic streptococcic infection in these 3 cases. The slight increase during convalescence in the antistreptolysin titer in case 4 and in the antifibrinolysin titer in case 6 were not regarded as significant. The leukocyte counts were either normal or only slightly elevated, and the per cent of polymorphonuclear leukocytes was normal. The exudate was not confluent. In 1 case it was confined to lymphoid follicles on the posterior pharyngeal wall, in another it was on the tonsils and in the third it was present both on tonsillar tags and on bands of lymphoid tissue on the pharyngeal wall. Enlargement of the cervical lymph nodes was not present. The course of illness was brief. In some of the patients the presence of cough, hoarseness, sputum, pleural pain and nasal symptoms indicated involvement of more than the oropharynx alone. None of these cases resembled a "typical" streptococcus sore throat.

The following case is one in which clinical differentiation between streptococcic and nonstreptococcic exudative tonsillitis was more difficult.

CASE 7 (Chart 6, E. H.).—A 20 year old soldier awoke June 9, 1943 with a sore throat, which resulted in considerable difficulty and pain in swallowing. He also noted cough and hoarseness and later became feverish and chilly, and a headache developed. On admission to the hospital the next day, he appeared to be moderately to acutely ill with a temperature of 102 F. The soft palate was edematous and the uvula resembled a distended bag of fluid. Both tonsils were covered with an exudate which was confluent on one side and discrete on the other. The mucous membrane, however, was not unusually injected. The anterior cervical lymph nodes were enlarged but not tender.

During the next four days the edema of the palate disappeared and the exudate cleared from the tonsils, but the latter did not regress in size. The cervical lymph nodes did decrease in size under observation. Fever and systemic symptoms disappeared on the fifth day of illness; sore throat, cough and hoarseness persisted for several more days.

The leukocyte count was moderately elevated. No evidence of beta hemolytic streptococcic infection was obtained from bacteriologic or serologic studies.

Although this was an instance of nonstreptococcic exudative tonsillitis, some of the features of the illness were those commonly found in streptococcic infections; these included decided edema of the uvula, confluent exudate on the tonsils and enlarged cervical lymph nodes. The correct diagnosis was entirely dependent on the laboratory tests.

The following case of nonstreptococcic exudative tonsillitis illustrates a commonly encountered pattern, in which the symptoms and course of illness resemble undifferentiated acute disease of the respiratory tract.[2c]

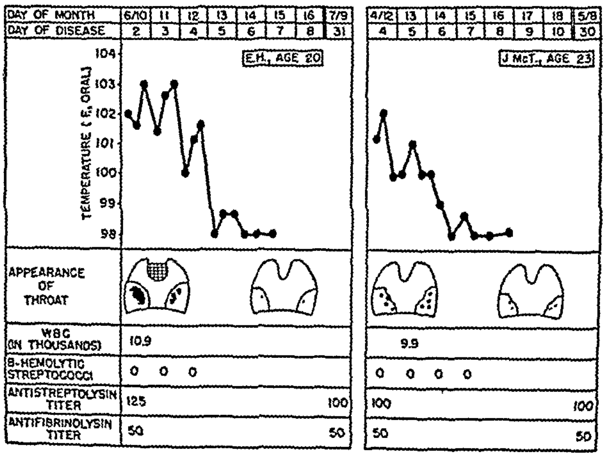

Chart 6.—Contrasting observations in 2 cases of exudative tonsillitis and pharyngitis of unknown origin: case 7, E. H., and case 8, J. McT.

CASE 8 (Chart 6, J. McT.).—A 23 year old soldier was ill for four days before admission to the hospital. The illness began gradually with cough, accompanied by substernal and costal aching. The next day there was generalized muscular aching, loss of appetite and later, fever, chilliness and headache. Sore throat and hoarseness developed shortly before hospitalization.

On admission the patient appeared only mildly ill and had a temperature of 101.2 F. The tonsils were enlarged, and on their surface were numerous discrete spots of exudate. The palate and posterior pharynx were entirely normal. The cervical lymph nodes were enlarged and tender.

The temperature fell to normal after three days in the hospital; systemic symptoms subsided with the fever. Sore throat, cough and hoarseness, however, persisted for several days more. The tonsils and the cervical lymph nodes decreased in size under observation. The bacteriologic and serologic data eliminated the possibility of streptococcic infection.

The gradual onset of symptoms and the prominence of cough, hoarseness and thoracic pain were features which are not unlike those found in undifferentiated acute disease of the respiratory system. Sore throat is also frequent in the latter condition. The development and pattern of the symptoms and the appearance of the throat were quite different from those characteristic of streptococcic infection.

The next case is an example of an unusually prolonged febrile illness associated with nonstreptococcic exudative tonsillitis.

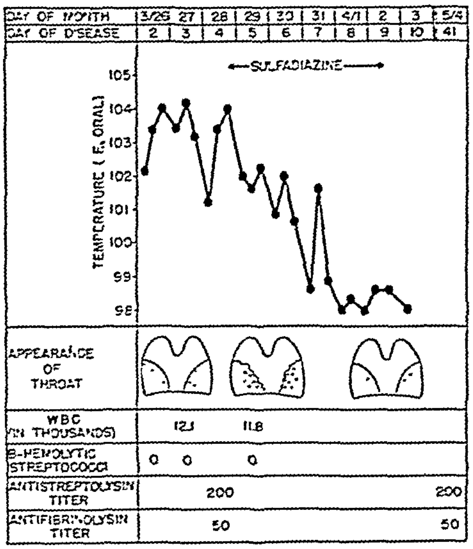

Chart 7. (case 9)—Exudative tonsillitis and pharyngitis of unknown origin with unusually high fever and prolonged course.

Case 9 (Chart 7).—An 18 year old soldier became feverish on the evening of March 27, 1944. The next day he continued to feel feverish, lost his appetite and had a sore throat and headache.

The temperature on admission was 102.2 F. The only abnormal physical observations were in the throat. The tonsils were not large but were diffusely red, and there were scattered small spots of gray-white exudate on them. The posterior pharyngeal mucosa was also injected, but the soft palate was normal. The next day the tonsillar exudate was more extensive, and the individual spots were larger. Over the course of the following week the exudate and redness of the mucous membranes gradually disappeared. The tonsils did not change in size. The anterior cervical lymph nodes were not enlarged during the illness and were tender to palpation on only one day.

The temperature was elevated to 104 F. for three days and did not regain the normal level until the eighth day after the onset of illness. During the febrile period systemic symptoms, sore throat, cough, hoarseness and substernal and costal aching were present. Because of continued fever sulfadiazine was administered (6 Gm. per day) for five days. During this period the temperature returned to normal; whether or not chemotherapy was responsible for this cannot be determined. The total leukocyte count was moderately elevated, but the percentage of polymorphonuclear cells was not abnormal. Laboratory studies eliminated the possibility of streptococcic disease.

This case illustrates that nonstreptococcic exudative tonsillitis may be associated with a considerable degree and duration of fever. In this instance, the severity and extent of the local inflammatory reaction in the throat did not seem adequate to account for the systemic reaction.

COMMENT

Greater recognition should be given to the fact that all cases of exudative tonsillitis and pharyngitis are not due to hemolytic streptococci. At this post, among recruits, less than half of such cases were proved to be of streptococcic origin. In general the distinction between cases of streptococcic and nonstreptococcic origin can ordinarily be made on clinical grounds, using as criteria the height of fever, the leukocyte count, enlargement and tenderness of the cervical lymph nodes, redness and edema of the mucous membranes and the extent and character of the exudate. Such criteria, however, are not infallible, and, as illustrated in some of the preceding case reports, may sometimes lead the examiner into error. For accurate diagnosis, cultural and serologic methods must be employed. These are particularly important in view of the fact that nonstreptococcic exudative tonsillitis and pharyngitis of the type described is a benign disease without recognized complications, whereas streptococcic infections of the throat may result in serious and crippling sequelae. Intelligent management of the cases, therefore, requires cultural and serologic confirmation of the diagnosis.

Results of bacteriologic tests alone may not be adequate for diagnosis. Many subjects, both normal and with respiratory disease, harbor hemolytic streptococci in the throat but do not exhibit streptococcus antibodies.[2b, c] Throat cultures taken from such carriers of streptococci usually reveal only a small number of these organisms. In contrast, cases of true streptococcic infection, in which an antibody response can be demonstrated in convalescence, frequently yield a predominant growth of hemolytic streptococci in throat cultures.[2a]

The cause of the type of exudative tonsillitis and pharyngitis herein described is unknown. Streptococcic infection can be ruled out with assurance on the basis of (1) multiple throat cultures yielding no hemolytic streptococci and (2) failure to demonstrate serum antibodies to hemolytic streptococci. The throat cultures made in these studies were also examined for other common aerobic organisms including pneumococci, staphylococci, Hemophilus influenzae, Klebsiella pneumoniae and Hemophilus hemolyticus. The frequency of occurrence of these organisms was the same in this group of cases as it was in well soldiers and in cases of undifferentiated acute respiratory disease.[2c] Serums from a sample of these cases were tested for the presence of type-specific pneumococcic agglutinins. Specific agglutinins of diagnostic significance were not found.[2a] Recently, in a few cases serum antibodies to H. hemolyticus have been demonstrated.[9] The etiologic significance of this observation is as yet unknown. At any rate, it does not appear that H. hemolyticus is the causative agent of infection in more than a small percentage of the cases, nor does it seem likely that any single bacterial agent can be incriminated as the cause of the majority of the infections. Presumably the disease is of nonbacterial origin.

---

[9] Mickle, W. A., in collaboration with the Commission on Acute Respiratory Diseases: unpublished data.

Nonstreptococcic exudative tonsillitis and pharyngitis has occurred in close epidemiologic relation to epidemics of undifferentiated acute respiratory disease among recruits at Fort Bragg. The cases have been widely distributed without evidence of focal concentration in small population units. Instances of the concurrence of exudative tonsillitis and pharyngitis and primary atypical pneumonia have also been found.[10] Others have previously reported an epidemiologic relationship between undifferentiated acute respiratory disease and nonstreptococcic exudative tonsillitis and pharyngitis.[1] Moreover there is a considerable degree of similarity in the clinical pattern of these conditions, when exception is made of those symptoms and physical signs which are related to the local inflammation in the throat. The leukocyte counts and the bacteriologic and serologic data in both conditions are not indicative of bacterial infection. It is suggested, therefore, that nonstreptococcic exudative tonsillitis and pharyngitis may be a variant of epidemic undifferentiated acute respiratory disease. Such a supposition would harmonize some conflicting opinions in regard to the relative incidence of exudative tonsillitis and pharyngitis of streptococcic and unknown origin in different geographic areas and among different military populations. At this post, streptococcic infections have been infrequent, and carrier surveys have indicated a low prevalence of hemolytic streptococci,[2b, c] while undifferentiated acute respiratory disease has been the chief cause of respiratory admissions.[11] Under these conditions exudative tonsillitis and pharyngitis of unknown cause have been more commonly seen than have true streptococcic infections among recruits. Conversely, in areas where hemolytic streptococcic carrier rates are high, and the military population is made up of seasoned troops, undifferentiated acute respiratory disease may be less frequent and streptococcic infections of the throat may occur more commonly than exudative tonsillitis and pharyngitis of unknown cause.[12]

From the present experience, no statement can be made as to the frequency of occurrence in civilian practice of exudative tonsillitis and pharyngitis of unknown cause. Because of its generally mild character, short course and freedom from complications, the suggestion may be advanced that it should be sought for among patients treated at home rather than in the hospital.

SUMMARY

Exudative tonsillitis and pharyngitis of unknown origin should be differentiated from streptococcic infections of the throat. The clinical differentiation can be made with reasonable accuracy in many cases but not in all. Accurate diagnosis demands the use of cultural and serologic methods. The salient features of these two types of exudative tonsillitis and pharyngitis have been presented, and cases have been reported to illustrate the variations in appearance and the difficulties in diagnosis.

RADIATION THERAPY OF UTERINE MYOMA

Critical Analysis of Results in Five Hundred Cases, Showing Indications and Limitations

ROBERT J. CROSSEN, M.D.
and
HARRY S. CROSSEN, M.D.
St. Louis

Some myomatous uteri cause no trouble and require no treatment. When there is undue bleeding, it may often be controlled by medication or by medication plus curettage. In cases which require more radical measures surgical removal is the treatment of choice in younger women and is also necessary for some myomas in older women. However, the use of radiation therapy in certain selected cases of the latter group has taken care of the myoma in many instances, without subjecting the patient to the risks of the major surgical operation of hysterectomy.

This study of our experiences in handling selected cases of myoma by radiation therapy (with curettage to exclude cancer and conization to remove chronic cervicitis) was undertaken to determine definitely the immediate and remote results of such treatment and to ascertain by a critical survey of results thus far attained if any modifications of our treatment plans were indicated. Selection of treatment in the various types of myoma depends not only on the long-recognized factors but also on the advances in knowledge which are made from time to time. One of these more recently recognized factors is the menace of silent carcinoma of the involuting ovary. Consequently it is important to determine in how many of these patients there developed ovarian cancer which would have been prevented by hysterectomy (provided the surgical procedure included bilateral complete oophorectomy, as it ordinarily should in climacteric patients). Also, does the radiation therapy, which stops myomatous activity and bleeding, shorten the period of erratic ovarian activity sufficiently to lessen the possibility that ovarian cancer will develop? Does the intrauterine radiation lessen the incidence of subsequent endometrial cancer? Does the conization remove the chronic irritation in the cervix sufficiently to give reasonable safety from cancer of the cervix?

The typical case for treatment by radiation is the medium-sized (fist-sized) myomatous uterus in a patient of climacteric age with bleeding as the principal symptom and with the pelvis otherwise clear. In the management of our cases individual contraindications to abdominal operation caused gradual enlargement of the radiation field in various directions—namely, in regard to the size of the growth, the type of pain associated with it and complicating adnexal inflammation. We advanced cautiously from radiation of fist-sized to larger growths and came later to include those grapefruit-sized (half way to the umbilicus). Even larger growths (up to the umbilicus) were treated by radiation to stop bleeding temporarily till the patient could be built up for abdominal operation. In some of these cases in which the tumor was exceedingly large the cessation of bleeding and the general improvement, with later relief of pressure symptoms, were so pronounced that surgical removal of the growth became unnecessary.

Read before the Section on Obstetrics and Gynecology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

As we begin consideration of this series of 549 cases of myoma selected for radiation therapy, a striking fact which emerges at once is that in 23 cases of myomatous patients the primary curettage revealed complicating carcinoma of the endometrium. This emphasizes the danger of treating an evident myoma with roentgen therapy or otherwise before ascertaining what complications may be present. This applies to treatment by hysterectomy as well as by radiation. We have been called in consultation to determine what should be done when, after supravaginal hysterectomy for "simple fibroid," complicating endometrial carcinoma was revealed by the routine pathologic report which was received some days later. This serious and trying dilemma would have been avoided if the surgeon had made a preliminary curettage or had decided beforehand to perform complete hysterectomy and bilateral oophorectomy.

TABLE 1—*Results in Five Hundred and Twenty-Six Cases of Myoma Treated by Radiation*

	Per Cent
Successful in stopping myomatous activity and associated symptoms	90
Direct failures; failed to stop myomatous activity and associated symptoms	7
Indirect failures, stopped myomatous activity, but surgical operation was needed later for some incidental development which would have been prevented by primary operation	3

TABLE 2—*Causes of Failures*

Type of Failure	Special Conditions Responsible			
Direct				21
In myoma			9	
	Submucous	4		
	Degeneration	4		
	Adenomyoma	1		
In uterus			4	
	Primary atresia and pyometra and metritis	1		
	Subsequent stenosis and pyometra and metritis	2		
	Beginning cancer inside cervix, missed in examination	1		
In adnexa			8	
	Chronic salpingitis	5		
	Endometriosis	2		
	Cancer of ovary	1		
Indirect				15
In uterus			6	
	Degeneration in myoma	2		
	Cancer of endometrium	4		
In adjacent structures			9	
	Simple cyst of ovary	2		
	Cancer of ovary	1		
	Appendicitis	6		

RESULTS

After we subtract the 23 cases in which complicating endometrial cancer was found at primary curettage and additional measures were instituted accordingly, we have left 526 cases in which radiation of the myoma was given a trial.

The term "radiation" as here used means the usual radiation dosage for stopping myomatous activity and all bleeding, including menstrual. This subject is large and ramified, and it seems inadvisable to complicate the discussion by adding the conservative use of radiation for bleeding in young patients who happen to have myoma. All 526 patients received the full myoma radiation dose. In nearly all cases the radiation was given as an intrauterine radium treatment in conjunction with the other uterine work and pelvic investigation. The exceptional instances in which roentgen therapy was employed were principally cases in which simple curettage had proved insufficient to stop the bleeding and roentgen therapy had been undertaken soon after, or those in which after a moderate radium dose some supplementary radiation was needed later.

In general the results have been very gratifying. We have been greatly pleased at the large proportion of patients who obtained complete and permanent relief. In exceptional cases in which myomatous activity or troublesome associated symptoms persisted, the necessary additional measures were employed. The statistical results are shown in table 1.

FAILURES

Of the 526 cases in which myoma radiation was given a trial, 21 were flat failures—that is, surgical intervention was later required for disturbances due to conditions presumably existent at the time of primary treatment, and which we hoped to take care of by the radiation. There were also 15 cases in which the radiation stopped the myomatous activity but in which surgical intervention was later required for conditions which would have been prevented if the primary treatment had been hysterectomy and bilateral oophorectomy instead of radiation. These 15 cases are counted as indirect failures. The details of these 36 failures are instructive.

Direct Failures (21).—The causes of these 21 direct failures are shown in table 2. The case of carcinoma of the cervix is of particular interest. The patient had a fist-sized myoma with bleeding. Pathologic examination of material removed at curettage revealed no malignant growth. Cervicitis was not evident, therefore conization was not performed. The radium dose was 2,000 mg. hours. The patient returned to her distant home and remained well for more than a year. Later some bleeding occurred at intervals, but it received no particular attention for several months until examination by her physician disclosed the cancer of the cervix and he sent her to us for the required treatment. It is probable that there was a small area of carcinoma within the cervix at the time of the primary investigation and treatment of the myoma and that it was missed in the curettage. The myoma dose of radiation checked the activity of the carcinoma temporarily, but later there was renewed activity and deep extension of the process.

In the case of ovarian carcinoma the patient, aged 55, had a grapefruit-sized myoma with bleeding. As she was a poor operative risk, radium treatment with curettage was employed in the hope that an abdominal operation could be avoided. There was fixation of the myoma, supposedly caused by adhesions from a former inflammation, and this interfered to some extent with deep palpation. The radiation therapy stopped the bleeding temporarily. Five months later recurrent bleeding and discomfort supposedly caused by the myoma led to abdominal operation, which revealed pelvic carcinomatosis of ovarian origin. The extent and type of carcinomatous involvement indicated that the ovarian cancer was present at the primary investigation and was missed in the examination. The fixation of the myomatous uterus and adjacent tissues which was supposedly the result of old inflammatory adhesions was in fact caused by the slow symptomless infiltration of an ovarian carcinoma. The penetration of the malignant growth was so widespread that only palliative measures were possible, and indications were that the process had penetrated beyond cure before the primary examination.

An embarrassing lesson which should not be overlooked is that 4 of the direct failures were due to failures in technic—in that of examination in 2 (a small area of carcinoma within the cervical canal was missed in 1 and an ovarian carcinoma in the other) and in that of intrauterine radium application in 2 (resulting in spot-devitalization, stenosis and persistent metritis requiring hysterectomy, from which, however, both patients made a good recovery).

Indirect Failures (15).—The causes of the indirect failures are shown in table 2. The appendix is removed incidentally in a considerable proportion of hysterectomies, and future appendicitis is thus prevented—therefore we assume that 6 of the 11 later appendectomies in this series would have been prevented if the primary treatment had been hysterectomy.

Though in these indirect failures radiation of the myoma was successful in stopping the myomatous activity and immediate associated disturbances, the fact that it did not prevent certain later incidental developments means that the relative possibility of these incidental developments must be considered in connection with the immediate risks of an abdominal operation when a choice of treatment is being made in a particular case. Also, the possible future developments are to be considered in providing later supervision.

The late development of 4 endometrial carcinomas and 1 ovarian carcinoma emphasizes the importance of regular pelvic check-ups and thorough investigation of any suggestive symptom. In the ovarian case the patient, aged 43, received a radium dose of 2,000 mg. hours for a grapefruit-sized myomatous uterus with a 4 inch (10 cm.) cavity. In addition to the curettage there was conization for chronic cervicitis. All bleeding, menstrual and otherwise, stopped in a month, and there was no more disturbance from the uterus. Two and a half years after the primary treatment an adnexal mass appeared, which at operation proved to be an ovarian carcinoma with some deep penetrations. The old myoma was inactive and atrophied. This case reveals the inadequacy of yearly check-ups, which were formerly considered safe protection. At our last check-up, seven months previously, we detected no evidence of ovarian growth. In this case deep palpation was difficult, but there was no suggestive symptom to indicate the need of palpation under anesthesia. Since our study[1] of "silent" ovarian carcinoma we have advised climacteric patients to come for pelvic check-up every six months, or sooner if any pelvic symptoms arise. That is the minimum requirement in providing safety from advanced incurable ovarian cancer.

Another important factor in the prevention of deaths from ovarian cancer is removal of the involuting ovaries whenever the abdomen is opened in the climacteric age (which may be considered to begin around the age of 42, with some individual variation in either direction). This item is discussed in detail elsewhere[1] as is also the fact that the advance of ovarian carcinoma is so insidious that the clinical picture is that of a slowly increasing ascites without localizing symptoms. In our series of 59 ovarian carcinomas 5 of the patients (nearly 10 per cent) had had a previous abdominal operation with an ovary left at ages 42, 43, 47, 53 and 56, respectively. The ovarian cancer appeared 12, 6, 6, 5 and 8 years respectively after the previous abdominal operation. In all 5 instances the ovarian cancer was advanced when discovered and proved fatal in less than a year. Removal of the involuting ovaries at the previous abdominal operations would have prevented the subsequent development of the ovarian cancers. Each of the 5 women clearly lost her life because an ovary was left at an abdominal operation in the age of involution. The insidious onset of ovarian carcinoma and its symptomless progress to incurability makes imperative the use of every means to prevent its onset.

In regard to whether or not radiation of a myoma reduces the incidence of subsequent uterine and ovarian cancer, consideration of the facts at hand indicates that there is a decided reduction of such incidence. Our records show 2,662 cases of uterine myoma, in 526 of which the patients received radiation of the myoma. Table 3 shows the development of endometrial cancer and of ovarian cancer in the two groups.

The 36 failures from various causes do not indicate that radiation fails to do what may reasonably be expected of it. They indicate only that the cases for radiation should be carefully selected and carefully followed, with the foregoing facts in mind. One learns as much from failures as from successes—perhaps even more.

Table 3.—*Ratio of Cancers in 2,662 Cases of Uterine Myoma*

Cancer of endometrium	
In 2,136 nonradiated cases of myoma	37 (1.7%)
In 526 radiated cases of myoma	4 (0.7%)
Cancer of ovary	
In 2,136 nonradiated cases of myoma	13 (0.68%)
In 526 radiated cases of myoma	1 (0.19%)

Each type of cancer was more than twice as frequent in the nonradiated cases as in the radiated.

SUCCESSES

The cases which followed a favorable course also can teach important facts which need consideration in the serious matter of advising a myoma patient what type of treatment is best for her in view of her special local and general conditions. Of the 526 cases in which myoma radiation was given a trial, 490 did well during the period of observation—that is, the troublesome symptoms of myoma were taken care of by the primary treatment alone or by the addition later of supplementary minor measures.

How long a period of favorable progress is required to indicate success of the myoma radiation? In this series the conditions interfering with the usual cessation of myomatous activity manifested themselves within a comparatively short period—50 per cent in two to six months, 35 per cent in the next six months and all within eighteen months; all who went eighteen months without evidence of interference with the usual postradiation involution had no important trouble in that respect later. A favorable course for two years seems fair as a criterion of success, as far as the cessation of ordinary activity of the myoma is concerned.

Of the 490 cases following a favorable course, 333 were observed for two years or more, running up to twenty years. Addition of the 36 failures (in the whole series to date) to the 333 favorable results in cases observed for two years or more gives 369 cases, with success in an estimated 90 per cent. Results were also favorable in 157 cases in which the period of observation was less than two years. It seems fair to assume that if they had been observed for the full two years the percentage of successes would have been about the same and would number 140. The addition of 333 plus 140 makes 473 radiation successes—that is, over 470 patients for whom we were able to accomplish with radiation and only minor risk what otherwise would have required a major abdominal operation with the serious risks it necessarily involves. That is no small accomplishment. It confirms an important advance in the therapeutic management of uterine myoma. Its attainment is well worth the careful study necessary to sound judgment in estimating the probable results in a particular patient, with the many variables to be considered.

---

[1] Crossen, H. S.: The Menace of "Silent" Ovarian Carcinoma, J. A. M. A. 119: 1485 (Aug. 29) 1942.

It must be kept in mind also that radiation is not necessarily the final step in treatment. It is given in a suitable case to stop myomatous activity, which it usually does. However, if the myoma continues to give trouble hysterectomy may then be performed in the knowledge that the abdominal operation is really necessary.

Table 4.—*Details of the Five Hundred and Twenty-Six Myoma Radiation Cases*

Size of the myomatous uteri		
Fist sized or smaller	456	Failures 31
Grapefruit sized	53	Failures 5
Near to umbilicus	17	Failures 0
Dosage		
1,200 to 2,400 mg hrs, depending on size and other factors		
Spot devitalization and metritis in 7 cases		
Advise moderate dosage, and supplement later if needed		
Supplementary radiation required in 23 cases with successful results		
Symptoms		
Cases with bleeding, 507 (96%), all but 14 were successful		
In the 19 nonbleeding cases—dysmenorrhea, 4; ovulation pain, 1; pruritus vulvae, 1; worried about the tumor, 1; pressure discomfort, discharge, 12		
Pain; ordinarily pain makes the case unfavorable; there are some exceptions		
Ages of patients		
Under 40	36	(7%)
40 to 50	318	(61%)
50 to 60	161	(30%)
Over 60	11	(2%)

Delayed menopause (age 48 to 58) has a sinister significance; in this series three fourths of the endometrial carcinomas occurred in the age period 48 to 58

Another advantage of radiation therapy in suitable cases is that it leads to treatment and thorough investigation at an earlier stage of the patient's disease. While the patient feels well and while only irregular periods or delayed menopause are associated with the fibroid she hesitates to submit to a major surgical operation and is inclined to postpone treatment. Also the physician, aware of the risks of hysterectomy, hesitates to press for immediate surgical intervention while the patient is well, and treatment is delayed. That was a common experience in the days when abdominal operation was the only effective treatment for uterine myoma. Now that we can in suitable cases stop activity of the myoma with only minor risk, patients submit to treatment promptly and welcome the opportunity of being relieved of their anxiety without a major surgical operation. The physician also, knowing the danger of delay and the absence of major risk, feels justified in urging prompt action in an early stage. The importance of early action in these cases is shown by the fact that 23 patients in this series had complicating endometrial carcinoma at the time of the primary investigation.

CONSIDERATION OF DETAILS

As an aid to careful selection and effective treatment, it is well to consider certain other factors in the 526 cases in which myoma radiation was given a trial. The items will be taken up in the following order: size of the myomatous uterus, dosage of radiation, supplementary radiation, symptoms in relation to choice of treatment, age groups of particular interest and associated measures.

Size of the Myomatous Uterus.—The statistics on size are given in table 4. In the compilation of our data we were astonished to find that all 17 patients with extremely large myomas (up to or near the umbilicus) for which radiation was given tentatively got along so well that removal of the growth was not necessary during the period of observation. Of these patients, 1 was observed for twenty years, 1 for fifteen years, 5 for five to nine years, 3 for three to five years, 2 for two to three years and five for less than two years.

Dosage of Radiation.—The fact that 2 of the direct failures were due to subsequent stenosis and pyometra and persistent metritis calls attention to the importance of the radiation dosage and its distribution in the cavity. The spot-devitalization which leads to subsequent small sloughs and later stenosis and pyometra, is caused not so much by a large dosage of radium as by its faulty distribution within the cavity. Wherever there is constriction and firm pressure of tissue against the radium tandem the devitalization effect is increased decidedly—hence, the internal os is the usual site of such trouble. Our experience indicates that with a constricting internal os (one that recontracts immediately after dilatation) it is well to limit the radiation in that particular area to about 500 mg. hours. In general it is well to give moderate dosage according to conditions, with the idea of some supplementary roentgen therapy later if needed, rather than to risk trouble from a heavy radium dose.

Ordinarily the postradiation complications of stenosis and pyometra yield to the office procedures of dilatation and tubal drainage, but not always. In this series of 526 patients there were 7 in whom this complication developed. In 5 cases the condition yielded to minor measures; in 2 chronic metritis persisted and required hysterectomy. All 7 patients eventually recovered.

Supplementary Radiation.—When after a radium treatment bloody discharge persists in spite of the use of antihemorrhagic medicaments or recurs after a few months it may usually be easily stopped by supplementary radiation with x-ray, which does not require hospitalization. For later bleeding, roentgen therapy may be used provided the time since curettage has not been so long as to raise the question of possible development of endometrial carcinoma in the meanwhile. This period varies in different types of disease, but in general it may be said that if the previous curettage showed endometrial hyperplasia recurrence after six months would indicate the advisability of another curettage. If the previous curettage showed normal endometrial tissue, simple roentgen therapy would suffice to control bleeding which recurred within a year, unless there was some factor to indicate otherwise. In the group of 490 cases that ran a favorable course during the period of observation there were 23 which required some supplementary radiation.

Symptoms.—The symptoms presented by a patient with myoma indicate the type of treatment most likely to prove effective. When bleeding is the principal symptom and the age of the patient permits use of the full myoma dose of radiation the situation is usually well controlled by it. When pelvic pain or pressure discomfort is prominent there is little likelihood of satisfactory relief.

Bleeding: The principal symptom in 507 of these patients was bleeding. The tendency may be manifested as excessive menstruation, intermenstrual bleeding or irregular bleeding after the menopause. A striking manifestation is the prolongation of fairly regular periodic flows beyond the normal menopausal age. This "delayed menopause" has a sinister significance; it indicates undue ovarian activity in the involutionary age, when erratic cellular activity is so likely to show a malignant tendency. This erratic activity of the cells is indicated by the presence of endometrial hyperplasia in these cases and by the frequency with which the hyperplasia has advanced to carcinoma in some portion of the endometrium. In our series, the curettages showed all stages of the progressive process from normal endometrium through endometrial hyperplasia to endometrial carcinoma.

Nonbleeding Myoma: As bleeding is usually the principal symptom requiring treatment in cases of myoma, it becomes of special interest to know what symptoms required treatment in the 19 cases of nonbleeding myoma shown in table 4. The 4 patients with dysmenorrhea were in the climacteric age; in all the pain was stopped by the radiation amenorrhea, as was also the ovulation pain and the menstrual pruritus. Most of the 12 patients with moderate discomfort due to pressure and with uterine discharge received some relief as a result of the radiation-induced cessation of myomatous and ovarian activity and later shrinkage.

A patient aged 51 with a large myoma extending to the umbilicus had no bleeding and no physical symptom of any kind. But she was worried about the growth, and it seemed that her anxiety might be less if she were given a course of treatment. For this reason a myoma dose of roentgen therapy was given, and arrangements were made for the regular twice-yearly observation visits. This relieved the patient's anxiety, and nothing disturbing happened during the subsequent five years of observation. At the end of that time the myomatous uterus was inactive and definitely smaller.

Pelvic Pain: When pelvic pain is an important feature in the symptomatology, myoma radiation will not give relief. However, there are exceptions, which may be identified by study of the type and location of the pain. In some patients the pain is exclusively menstrual, coming only with the periods and consisting of typical "menstrual cramps." Radiation amenorrhea relieves this type of pain and also ovulation pain.

Ordinary pain between periods is not likely to be stopped by myoma radiation, for it is usually due to some complicating condition over which radiation therapy has little or no control. Chronic adnexal pain is the most commonly encountered. Another type of chronic inflammatory condition to be aware of is the pathologic appendix. When there is any suspicion of chronic appendicitis gastrointestinal roentgenologic examination is indicated to determine the condition of the appendix before deciding on radiation for the myoma.

Ages of Patients.—The ages of the 526 patients who received myoma radiation are shown in table 4. It is significant that 30 per cent of these patients were in the fifties, an age when normally the menopause is past and ovarian involution well advanced. Myomatous activity is supposed to be due to ovarian activity. Why then this large number of patients requiring radiation for myomatous activity at an age when ovarian activity normally ceases? The answer is that in these cases of myoma ovarian involution does not proceed in the normal way.

Delayed Menopause.—The myoma keeps up uterine and pelvic congestion and erratic ovarian and endometrial activity long after these temporary organs should have ceased to function. Hence the frequency of delayed menopause and endometrial hyperplasia and the associated tendency to endometrial carcinoma (corpus cancer). Some years ago, Dr. Hobbs and one of us (R. J.) analyzed[2] a series of 56 cases of carcinoma of the corpus uteri in which the age at menopause was known. We found that the menopause was delayed to age 50 in 60 per cent of these malignant cases, whereas in a series of women without cancer the menopause was delayed to age 50 in only 15 per cent. In a recent article by Randall[3] attention has been called to the frequent association of delayed menopause and cancer of the corpus uteri. He found that in a series of 113 such cases the menopause was delayed to age 51 in 35 per cent, while in his nonmalignant cases the menopause was delayed to age 51 in only 8 per cent. The percentages of these two investigations correspond closely, considering that the later investigation is based on an additional year of menopausal delay. Notice that in both series the percentage of delayed menopause in malignant cases was four times that in the nonmalignant.

Table 5.—*Measures to Prevent Deaths from Uterine and Ovarian Malignancies*

1. Conization whenever chronic cervicitis is present
2. Investigation of delayed menopause by curettage; (endometrial cancer is found four times as often in cases of delayed menopause as after normal menopause)
3. Regular check-up examination twice yearly in climacteric age, to detect the symptomless infiltration of ovarian carcinoma
4. Removal of involuting ovaries whenever the abdomen is opened in the climacteric age; (in our series of 59 ovarian cancers, 5 of the women had had abdominal operation with an ovary left in at the age of involution)

ASSOCIATED MEASURES

When arranging for radiation therapy for a uterine myoma, provision should be made also for certain associated measures. There are four accessory steps necessary for the safe handling of the case. They are (1) deep pelvic palpation under the anesthesia, (2) curettage, (3) conization when chronic cervicitis is present and (4) accurate recording of the examination findings in the operative note.

1. *Deep Pelvic Palpation.*—The anesthesia for the curettage gives opportunity for deep palpation of the ovarian areas, and the anesthesia should be increased sufficiently to give good relaxation to facilitate this. The

importance of deep palpation under anesthesia is not fully appreciated until one has had the harrowing experience of having a patient return with irremovable ovarian carcinoma which was missed at the primary investigation because the ovarian enlargement was too small at that time to be detected through a resisting abdominal wall.

2. *Curettage.*—The 23 cases of complicating endometrial carcinoma discovered at the primary curettage constitute sufficient comment on the importance of this measure. The curettage should cover the walls of the cavity carefully and systematically, so that if there is only a small area of carcinoma it will not be missed. Of course all the tissue removed must be saved, otherwise there is no certainty of excluding the possibility of cancer, for malignant growth may be present only in the small discarded particles. A moment's thought will show the fallacy of depending on the pathologic report on part of the material removed by curettage to exclude the possibility of cancer, and yet this "picking out of suspicious pieces" may still be seen in operating rooms.

3. *Conization.*—Complicating chronic cervicitis was treated by conization, along with the application of radium for the myoma. The conization excluded the present existence of cancer in the cervix and aided in preventing it in the future by removal of the source of chronic irritation, which is so dangerous in the climacteric period. In this series of 526 cases of myoma treated by radiation 233 of the patients had chronic cervicitis which was treated by conization. No cancer has been reported among those with conized cervices. The case of cancer of the cervix previously described in detail occurred in a patient in whom conization had not been performed.

4. *Accurate Recording.*—When the patient who has not been seen for a year or two returns, pelvic examination may show that an ovary is somewhat enlarged. In view of the insidious onset and symptomless progress of ovarian carcinoma, the physician wonders if the enlargement is a new growth or an old enlargement of no importance and turns anxiously to review the pelvic findings at the time radiation therapy of the myoma was given. Unfortunately, accurate deep palpation under anesthesia and itemized recording of observations did not seem important at that time, when attention was focused on the radiation therapy—so there is no definite record of the former condition of each ovary. Experience is a great teacher, and the lack of accurately recorded data causes serious dilemmas, which alert the physician to his responsibilities.

SUMMARY AND CONCLUSIONS

Any major addition to the therapeutic management of an important disease entity requires clinical confirmation of its adaptability and effectiveness under the various physical and psychologic conditions of actual practice and in critical comparison with other methods which are available. In the use of radiation therapy in selected cases of uterine myoma in women of climacteric age there is now a sufficient accumulation of carefully observed cases to justify deductions as to its indications and special requirements. This study of our experiences is a contribution to the factual assessment of its advantages and limitations.

1. In this series of 549 cases of myoma with conditions apparently favorable for the treatment of the myoma by radiation, the primary curettage revealed that 23 patients had complicating endometrial carcinoma.

2. Success was attained in 90 per cent of the 526 cases in which myoma radiation was given a trial. The failures were of two kinds—direct (7 per cent) and indirect (3 per cent). The direct failures were those in which the radiation failed to stop the myomatous activity and associated troublesome symptoms. In the indirect failures, the radiation stopped the myomatous activity and associated symptoms, but surgical intervention was later required for some incidental development which would have been prevented if the primary treatment had been complete hysterectomy and bilateral complete oophorectomy.

3. The 90 per cent of successes means that for over 470 patients we were able to accomplish with radiation therapy and only minor risk what otherwise would have required a major abdominal operation.

4. It must also be kept in mind that radiation is not necessarily the final step in treatment. If the myoma of the uterus continues to give trouble, hysterectomy may then be carried out in the knowledge that the risks of abdominal surgical operation are justified. It is easy to advise hysterectomy, but when things go badly it is not easy to restore the patient to life for a trial of radiation therapy, which might have proved sufficient.

5. Another advantage of treatment by radiation in suitable cases is that it leads to treatment and thorough investigation at an earlier stage of the patient's disease. The importance of early action in these cases is shown by the finding of endometrial cancer in 23 of these myoma patients at the primary investigation.

6. In the overall results secured certain associated measures have an important part. These associated measures are: (1) deep palpation of the ovarian areas under the relaxation of anesthesia, (2) curettage to determine if there is any intrauterine complication, (3) conization when there is chronic cervicitis and (4) accurate recording of the findings in the examination under anesthesia, for future reference in the event that the patient returns with new bleeding or a suspicious adnexal mass.

ABSTRACT OF DISCUSSION

Dr. William E. Costolow, Los Angeles: Dr. Crossen has given us an unbiased analysis of the question of choice of treatment in fibroid tumors. He has shown that the careful selection of cases is the most important single factor contributing to success in the treatment of fibroids by radiation therapy. The diagnosis of uterine myoma should be definitely established before radiation therapy is commenced. If doubt exists in regard to the diagnosis then surgical intervention is the treatment of choice. Radiation has been used successfully for many years in the treatment of certain uterine fibromyomas. Contraindications to its use have been established for many years. Some of these are quite definite—others possibly are too rigid to be exactly substantiated, and patients for radiation therapy are no doubt being selected too conservatively. Some time ago the Los Angeles Tumor Institute reported 1,009 cases of fibroid tumors treated by radiation methods. The average age of the patients was 43.2 years, and 75 per cent were over 40 years of age. Of 722 fibroids which were not larger than a three months pregnancy, there was reduction of the uterus to a size normal or only slightly enlarged in 93.5 per cent of the patients. Only 2.4 per cent of these patients were operated on later. The findings at opeartion were as follows: 3 ovarian cysts, 3 submucous fibroids, 3 carcinomas of the fundus, 1 carcinoma of the cervix, 1 intestinal obstruction and 4 with no relief of pressure symptoms. In a group of 264 cases the tumors were the size of a 4 months pregnancy or larger. Tumors of this size are usually considered to require surgical intervention. Results of radiation treatment in this group were not poor, as only 4.2 per cent later needed surgical intervention because in 7 there was no reduction in the size of the mass, in 1 there was an ovarian cyst, in 1 a dermoid cyst and in 2, degeneration of the mass. Mistakes in diagnosis are the common cause of failure in fibroid irradiation. In only 4 cases in the entire series, or 0.04 per cent, did cancer develop later. This figure is lower than that for the normal incidence of uterine cancer in women with an average age of 43.2 per cent. Dr. Crossen has again demonstrated by his excellent results that radiation therapy is a most satisfactory method of treatment in properly selected cases of uterine fibroids.

Dr. Charles E. Galloway, Evanston, Ill.: The paper brings up a controversial subject, and I think that the controversy should be continued in an orderly and gentlemanly manner. Radiation for fibroids comes and goes as a treatment, like veratrum viride in the treatment of eclampsia. Many of us have long since discarded it and continue to reject it because we do not think that it is fundamentally sound. I would like to ask Dr. Crossen what the mortality rate was in this series. I did not hear it mentioned. I feel that there is mortality, and I also feel that there is a fairly large morbidity, both acute and chronic, following radiation. Women who have had radium inserted into the uterus may come in years later with an extremely irritable bladder or an irritable rectum. It causes a late obliterative endarteritis that results in a great deal of discomfort. In the desire to do away with temporary symptoms, sight must not be lost of the ultimate discomfort that may be caused. I do not believe that other physicians, either, will agree that women who have had radium used for the treatment of small uterine fibroids are less apt to develop cancer of the uterus. A recent survey by Dr. Corscaden in New York would tend to show that such women are about three times as apt to have a carcinoma of the fundus of the uterus develop later on than are women who have not had radium applied, and in my opinion that factor should be considered. A favorable course for a period of two years is not sufficient to evaluate results in a patient; one must consider that woman until she dies, and until one gets those complete statistics one will not have the ultimate answer. Twenty-three patients had to have another dose of radium. We hear mentioned, too, in this discussion, the words, "the high mortality of major surgery." I do not think that hysterectomy carries with it a high mortality rate. If a woman has a small fibroid tumor in the uterus and it is giving her trouble, she is much safer in having it removed than she is in having it dealt with by the application of some foreign element into her body in order to bring about a certain physiologic change. The appendix has no place in gynecology, and what might have occurred to the appendix is a secondary consideration. Any one performing a surgical operation in the abdomen is better off if he lets the appendix alone; and personally, I remove most uteri with small fibroids through the vagina. This is a controversial subject and should be discussed. I think Dr. Crossen has made up his mind about what he wants to do, but I want it understood that some of us do not agree with that decision.

Dr. Clyde K. Emery, Los Angeles: I wish to ask Dr. Crossen if a uterine myoma or a fibroid can become malignant? I have never heard of a case where a cancer develops in a fibroid. In my opinion there is not a significant difference between the incidence of cancer of the uterus before and after radiation therapy. But the two significant things that should be considered are that when radium is inserted the physician has a good chance to do a dilatation and curettage. Many times, when subtotal hysterectomies are to be performed, they are not preceded by a diagnostic curettage. It has been my experience, like that of every one else doing radiation therapy, that cases are referred in considerable numbers in which the carcinoma of the cervix or the endometrium has been diagnosed by the pathologist following the removal of the upper part of the uterus. Another point that Dr. Crossen mentioned is the possibility of doing a good conization of the cervix at the time the radium is inserted. I noticed that only half or a little over half of the patients that he had treated had a conization, and I have always considered that it was a most effective way of preventing the development of a carcinoma of the cervix in the future. I wonder if Dr. Crossen would not consider that conization was a good routine procedure to carry out in every case.

Dr. J. L. Bubis, Cleveland: The question of using radium in the treatment of fibroids has been controversial. There are clear indications for the use of radium in the treatment of certain types of fibroids, especially in the intramural type. Its use is not advised in the intraligamentary, the pedunculated subserous or degenerative type of fibroid, in which a slough very often follows. Some fibroids are calcified, and the use of radium does not help much in those cases. Old, chronic pelvic inflammations may also be rekindled by radium therapy. With improved surgical skill, technic and care, including transfusions, intravenous dextrose and so forth, total hysterectomies and the removal of diseased adnexa often give much more satisfactory end results than can be obtained by the use of radium. I usually remove the appendix unless it is of the involuting type, contrary to the procedure of Dr. Galloway. In some extremely difficult cases I have occasionally left the appendix in, but I have had to subject a number of these patients to subsequent surgical operations. There are certain indications for radium therapy in the treatment of fibroids of the uterus, but I believe that the indications for its use are less than those enumerated by Dr. Crossen.

Dr. R. Luikart, Omaha: The ultimate results in the treatment of fibroids depends on proper selection of the cases and proper radiation as stated by Dr. Crossen. If a patient with a uterine fibroid complicated by pelvic inflammatory disease is treated with radium, the results, to say the least, are likely to be unsatisfactory. That is the fault not of the radium but of the selection of the case. When the uterine fibromyoma is properly selected the treatment with radium gives relief to the patient with much less of danger, discomfort, mortality and morbidity, hospitalization and expense and with much more rapid recovery than does a surgical operation.

Dr. Robert J. Crossen, St. Louis: Dr. Galloway brought out Dr. Corscaden's figures. Dr. Corscaden has not limited the type of patient in his series at all. He includes all benign bleeding and has mentioned no conizations; hence I do not believe his series applies to this particular subject. We have limited our series to fibroids, selected our cases carefully and insisted that certain procedures be followed out, namely, curettage to rule out endometrial carcinoma, conization to get rid of chronic cervicitis and so forth. We are doing conization in more cases now than we did previously and most of our patients are conized at the time of the curettage and radium treatment. It is only by careful analysis that real facts can be determined. I don't think any one can say, as they do so frequently in meetings, "I have a feeling that over a period of so many years such and such is true." For that very reason we went into detail and carefully analyzed this large series of cases, which extended over a period of twenty years, bringing out the failures and the reasons why they were failures, to see if we could not get some accurate statistics on this subject. I am only hoping that this work will stimulate report of a further series of this kind.

Glanders.—Primarily an equine disease, glanders occurs naturally in two forms, namely acute or chronic systemic glanders and cutaneous glanders. In the past the disease in man has usually been contracted by direct or indirect contact with infected horses. During the past thirty years, however, owing to constant testing of horses and eradication of infected animals, this disease has been rare in this country. The only case known by the writers to have occurred in the United States in recent years was described by Herold and Erickson in 1938. The disease occurs more frequently in Russia, the Balkans and parts of Asia and Africa where veterinary control measures are less stringent or nonexistent. A number of accidental infections have been recorded in the past among laboratory workers.—Howe, Calderon, and Miller, Winston R.: Human Glanders: Report on Six Cases, *Ann. Int. Med.*, January 1947.

CEREBELLAR AND SPINAL INJURIES AFTER CHIROPRACTIC MANIPULATION

H. R. PRATT-THOMAS, M.D.
and
KNUTE E. BERGER, M.D.
Charleston, S. C.

Several maleficent results of cultist mechanotherapy have been reported.[1] We wish to describe 3 cases including necropsy observations in which cerebellar and spinal injury occurred. Careful search of the literature leads us to believe that at least 2 of these are unique, as no other comparable cases have been found.

REPORT OF CASES

CASE 1.—*History and Course.*—A white man aged 32, a boat captain, had been complaining of persistent headaches and an occasional "giddy" feeling and nausea for four weeks. He had been working continuously running his boat. During the two weeks prior to admission he had been going to a chiropractor frequently for "adjustments." The afternoon prior to admission he felt as usual but went for another "treatment." During the course of the manipulation he became unconscious, and a physician was summoned. He was admitted to the hospital at 3 p. m. Feb. 10, 1941. On admission his blood pressure was 135 systolic and 60 diastolic, his pulse rate 74, his respiratory rate 24 and his temperature 97.4 F. He was well developed and well nourished. He was restless, moving about frequently and showing generalized clonic tremors. The pupils were round, regular and equal and responded to light. The tongue was in the midline, and the neck was freely movable, without pain or tenderness. Examinations of the lungs, heart and abdomen revealed essentially normal conditions. The reflexes were as follows: left biceps 3 plus, right biceps 2 plus and patellar 4 plus bilaterally. There was bilateral ankle clonus, and the great toe reflex was positive bilaterally.

Laboratory examinations revealed an erythrocyte count of 5.15 million with 90 per cent hemoglobin. The white blood cells numbered 16,600 with 85 per cent polymorphonuclears. Catheterized urine was normal. Roentgenograms of the neck revealed no evidence of fracture or dislocation. A lumbar puncture six hours after admission showed an initial pressure of 270 mm. of water. Pressure on each jugular vein resulted in a rise to 290-300 mm. followed by a fall to 280 mm. Bilateral compression resulted in a rise to 350 mm. with sluggish fall. The cytology of the spinal fluid showed 10 white blood cells, of which 60 per cent were lymphocytes, and 156 red blood cells per cubic millimeter. Tests for globulin and sugar were negative.

Later in the evening it was noted that the patient held his head to the left and that any change in its position caused cessation or interference with respiration. The lower extremities became spastic, while the upper extremities became flaccid. Virtually no voluntary movements were observed. The cranial nerves were intact but the optic disks showed loss of physiologic cupping.

A lumbar puncture the next morning showed an initial pressure of 169 mm. of water. On right jugular compression it was 170. On left jugular compression it was 168, and on bilateral jugular compression it was 164 mm. The blood pressure was 170 systolic and 50 diastolic, and the pulse was bounding. During the night the patient had required catheterization. Hyperthermia had developed despite sponging, and terminally the temperature reached 107 F. The patient expired twenty-four hours after admission. The clinical diagnosis was "contusion of the medulla oblongata with complete block."

Pathologic Observations.—Necropsy was performed two hours after death. The body was that of a well developed and well nourished white man showing no external evidence of injury. The calvarium and skull showed no evidence of fracture. The brain was edematous with decided flattening of the convolutions and narrowing of the sulci. The vessels over the brain stem were thin-walled and pliable, but fairly firm clot was present in the basilar, left anterior inferior and right posterior inferior cerebellar arteries (fig. 1 *A*). The cerebrum appeared normal except for edema. The cerebellum was softer in consistency than normal, and horizontal section revealed greatly softened brownish gray tissue occupying a portion of the left lobe of the cerebellum and measuring 3.5 by 4.5 cm. (fig. 2). This also was present in the left cerebral peduncle and pons. Within the right lobe of the cerebellum there were similar multiple areas of softening. The fourth ventricle was compressed to a practically imperceptible slit. There was a moderate cerebellar pressure cone and slight notching of the hippocampal gyri. The lateral ventricles were not dilated.

The interior of the cervical portion of the spinal canal was smooth, and palpation showed no dislocation or unevenness. The ligaments of the atlas and axis allowed some movement, and it was thought that they were more lax than usual. There was no dislocation of the odontoid process, and the medulla showed no evidence of trauma.

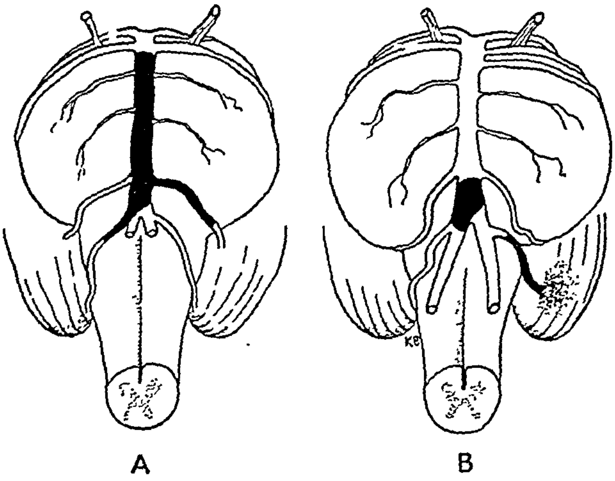

Fig. 1*A*—Diagram of basilar artery in case 1 showing thrombus (black) in basilar, left anterior inferior and right posterior inferior cerebellar arteries. *B*, case 2, showing thrombus in basilar, right vertebral and left posterior inferior cerebellar arteries with softening of the left tonsil.

Histologic Data.—Sections confirmed the recent but definite antemortem thrombosis of the basilar, anterior inferior cerebellar and posterior inferior cerebellar arteries (figs. 1 *A* and 3). There were areas of frank necrosis in the cerebellum, cerebral peduncle and pons with multiple punctate and linear hemorrhages. The large areas noted grossly showed extensive necrosis with complete disintegration of cell architecture and much erythrocytic extravasation. Foci of intracellular and extracellular edema with early softening were also visible. Hemorrhages were most conspicuous in the periphery of the right lobe of the cerebellum (fig. 4). Occasional collections of leukocytes were present in the necrotic and hemorrhagic areas. Many of the small vessels contained thrombi and a few showed necrosis of their walls with heavy leukocytic exudation. There was no evidence of arteriosclerosis or syphilis.

CASE 2.—*History and Course.*—A white woman aged 35 had been periodically visiting a chiropractor because of "hay fever." After a "treatment" on March 2, 1945 she complained of feeling "dizzy," and at the suggestion of the chiropractor she remained for further treatment. On March 3 she was taken to her home in an unconscious condition by the chiropractor at 1 p. m. He instructed the family to take her to a physician. She was

S.: Manipulative (Chiropractic) Dislocations of the Atlas, ibid. **85:** 1356-1359 (Oct. 31) 1925. Fisher, E. D.: Report of a Case of Ruptured Intervertebral Disc Following Chiropractic Manipulation, Kentucky M. J. **41:** 14 (Jan.) 1943.

brought to the hospital in an unconscious state and expired that night at 10:30 p. m. Details of the clinical findings are not available.

Pathologic Observations—Necropsy was performed fourteen hours after death. The body was that of a well developed, well nourished white woman. External examination reveals no evidence of trauma. Except for pulmonary edema, the gross findings were limited to the head.

The calvarium was intact and after opening the intact dura the convolutions and sulci were seen to be well defined. The cerebellar tonsils protruded into the foramen magnum, and their tips showed hemorrhagic discoloration and softening (fig. 5). This cerebellar pressure cone was very prominent, measuring 1.5 cm. in height and being somewhat more sharply defined on the right There was also softening of the adjacent left cerebellar hemisphere Careful examination of the skull after stripping away the dura revealed no evidence of fracture. There was increased mobility of the first and particularly the second cervical vertebra, the first articulating more freely against the occipital condyles than is usual. The cervical spinal cord was removed by means of a posterior approach and showed no evidence of hemorrhage or softening in its substance.

Microscopically the cerebellum showed disruption of tissue in the peripheral area with multiple punctate and linear hemorrhages There was edema and softening of the cerebellar substance, with thrombosis of the posterior inferior cerebellar artery which led directly to one of the areas of softening (fig. 6). Early thrombus was also found in the basilar and right vertebral arteries (fig 1 *B*). The vessels showed no other abnormality that could have been contributory in any way. There was also definite cellular swelling and widening of tissue interstices, with vacuoles about nerve cells and between fibers and with focal areas of early softening in the cerebellum, medulla and upper part of the cervical cord.

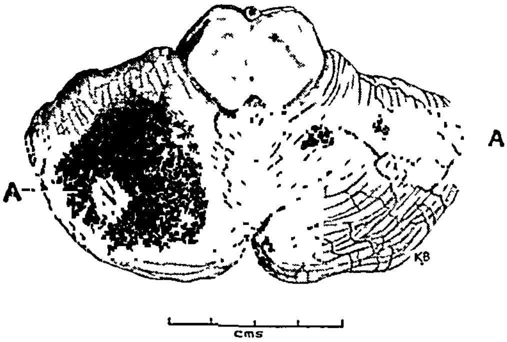

Fig. 2 (case 1)—Superior aspect of cerebellum showing multiple areas of hemorrhagic softening (*A*).

Case 3—*History and Course.*—A white man aged 31, employed as a rigger, noted severe pain in the neck and chest after carrying a piece of steel up three flights of stairs on Aug. 12, 1945. The pain was not relieved by anodynes He went to a chiropractor, who told him he had a nerve out of place and that he would require several treatments During the fifth treatment, about four days before admission, the patient states that his back was "mashed" and shortly afterward there developed increasing weakness and numbness of his legs The day before admission he was unable to walk.

On admission Aug 31, 1945 examination disclosed a well developed and well nourished white man with a blood pressure of 120 systolic and 80 diastolic, a temperature of 100 F., a pulse rate of 90 and a respiratory rate of 18 He was able to move his left leg but could move the right leg only with great difficulty. During the next three days there developed complete paralysis of both lower extremities with absent reflexes and loss of pain sensation up to the level of the nipples. The spine was stiff. The patient was unable to void and required catheterization; he stated that he had no control of his anal sphincter.

Roentgenograms of the cervical, thoracic and lumbar spine were negative except for a slight rotatory curvature of the third, fourth and fifth thoracic vertebrae. There was no evidence of fracture or dislocation of the spine.

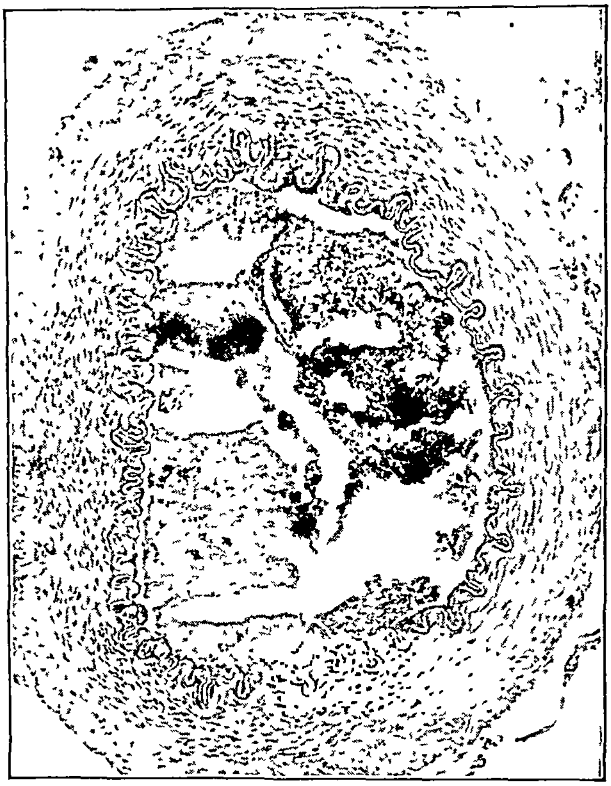

Fig. 3 (case 1)—Basilar artery showing thrombus partially filling its lumen Hematoxylin and eosin, × 60.

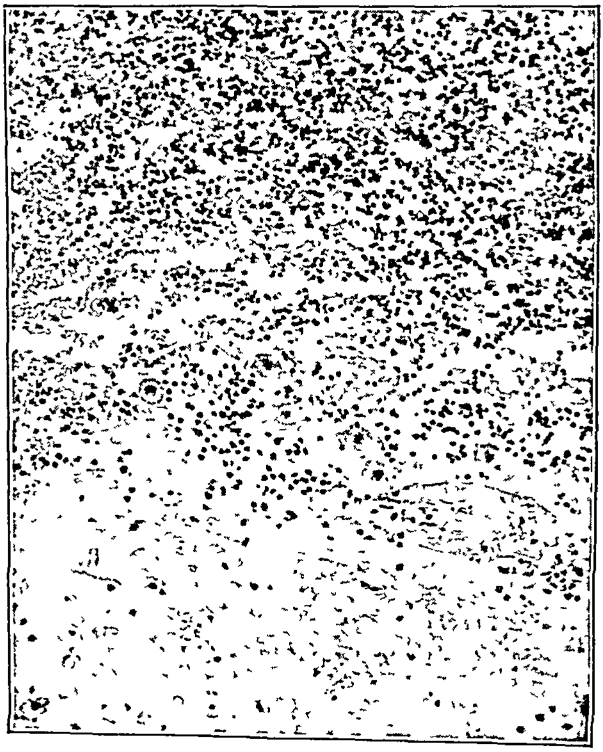

Fig 4 (case 1)—Perivascular and irregular linear hemorrhages in cerebellum Hematoxylin and eosin, × 150.

The blood Wassermann test was negative. Lumbar puncture revealed an initial pressure of 74 mm. of water with free flow of spinal fluid. On jugular compression the pressure rose to 110 mm. The fluid was clear but contained 37 cells per cubic millimeter, 20 per cent of which were polymorphonuclears and 80 per cent lymphocytes. The total protein was 422 mg. per hundred cubic centimeters. Kolmer and Kline tests of the spinal fluid as well as the colloidal gold curve were negative.

Shortly after admission of the patient there developed a febrile course associated with chest pain, dyspnea, pulmonary rales and a cough productive of mucoid sputum. The respiratory difficulty increased, and cyanosis persisted despite the administration of oxygen so the patient was placed in a respirator. He became irrational and died of sepsis on the seventeenth hospital day.

Pathologic Observations.—Necropsy was performed five hours post mortem. The body was that of a well developed but rather poorly nourished white man with decubitus ulceration. There was a pulmonary abscess 3 cm. in diameter in the peripheral portion of the right middle lobe with a right empyema.

Examination of the head and neck disclosed no evidence of trauma. *The brain, meninges and cerebral vessels showed no* pathologic changes. The spinal cord was removed, and a reddish membranous area 5.5 cm. in length was found covering the external surface of the posterolateral aspect of the dura beneath the laminas of the first and second thoracic vertebrae. Nine centimeters below the medulla there were prominent vascular markings and softening of the center and left half of the cord (fig. 7). As the cord was sectioned downward there was well defined softening and brownish discoloration, and at a point 15 cm. below the medulla the entire cord was soft and discolored. Below this for a distance of 17.5 cm. practically the entire cord was soft and brownish, with hemorrhages about the canal in its posterior aspect. No vertebral fracture or dislocation was found. The dura was intact.

Microscopically there was hemorrhage within the dura as well as on its external surface, which showed organization with a layer of granulation tissue containing fibrocytes, lymphocytes and macrophages. Selected sections of the spinal cord showed variable degrees of necrosis, varying from rather well demarcated focal areas to practically complete destruction of cord tissue with scattered hemorrhages and extensive gitter cell reaction (fig. 8). The anterior and dorsal spinal nerves also showed degeneration.

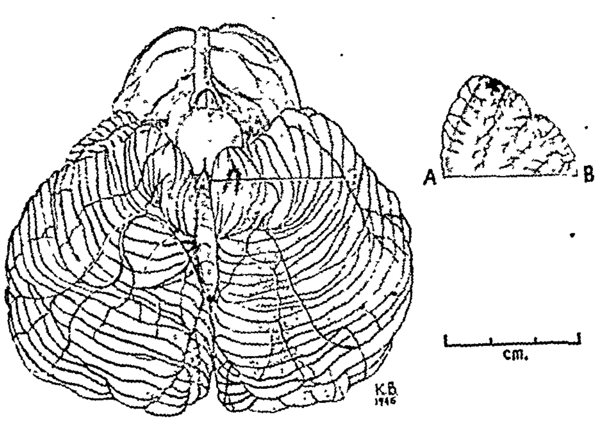

Fig. 5 (case 2).—Swollen, herniated, contused tonsils of cerebellum. Stippling represents areas of softening.

COMMENT

These 2 instances (cases 1 and 2) of isolated cerebellar contusion seem unique, as review of the literature reveals no similar cases. It is difficult to give an unequivocal explanation of the mechanism productive of these injuries, as we do not know the exact application of the injuring forces. In these cases there is considerable evidence that the damage done to the cerebellum and brain stem was produced by impairment of the blood supply as well as by direct trauma.

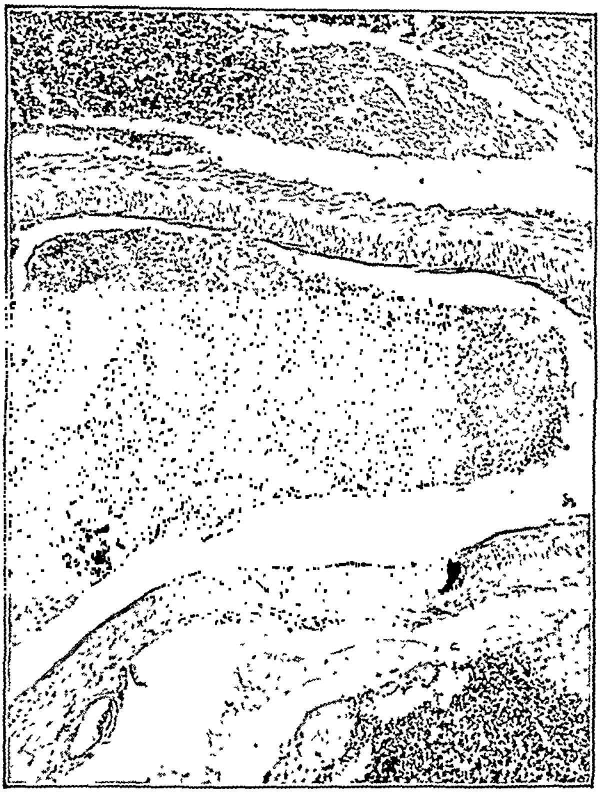

Fig. 6 (case 2).—Thrombosis of posterior inferior cerebellar artery. Hematoxylin and eosin, × 75. Photomicrograph slightly reduced from a magnification of × 75.

It is established that thrombosis of normal as well as abnormal arteries and veins may occur as a result of various traumas such as blunt injury (contusion)[2] or muscular strain.[3] Intracranial vessels may be more susceptible in that the extracerebral intracranial vessels are not supported by surrounding tissues and have a less developed elastica externa and adventitia than have other peripheral arteries.[4] Fibrin thrombi in cerebral vessels have been reported in concussion.[5] Also it is possible that there is a vasospastic element in cerebral vessel thrombosis[6] which may aggravate the effects of partial occlusion. Although occlusions of the basilar and/or cerebellar arteries have been described,[7] we have found no descriptions in the literature related purely to trauma, the thromboses previously described being associated with vascular disease, rheumatic fever, syphilitic endarteritis and septicemia.

Thrombosis of nutrient vessels is demonstrable histologically in our cases. The mechanism by which thrombosis was produced is speculative, but there are several

possibilities. As the involved vessels were peripherally situated they could have been damaged by manipulations that forcibly brought them into contact with the cranial case. That contusion of the surface of the cerebellum did occur is shown by disruption of architecture and hemorrhages in its superficial substance. Distortion with partial or complete occlusion of either of the vertebral arteries or the basilar artery could conceivably have the same effect. Occlusion of the basilar or vertebral arteries so as to include one or more of the cerebellar branches might result in sufficient focal cerebellar ischemia to cause the lesions found in these 2 cases. The mechanism by which vertebral or basilar arterial injury or temporary blockage might be caused is also problematic. Great extension and flexion of the head produces changes in the configuration of the cranial outlet. Lateral movements and rotation also alter its shape, but to a less extent than pronounced extension. Extension results in narrowing of the craniospinal aperture due to a change in the relationship of the atlas and base of the skull. Such a mechanism might produce pressure on the basilar or vertebral arteries and actually injure their walls; particularly as these vessels are in close proximity to the foramen magnum and basilar portion of the occipital bone. We consider that repeated and aggravated changes in the shape of the cranial aperture may have a definite bearing on the vascular phenomena observed in these 2 cases.

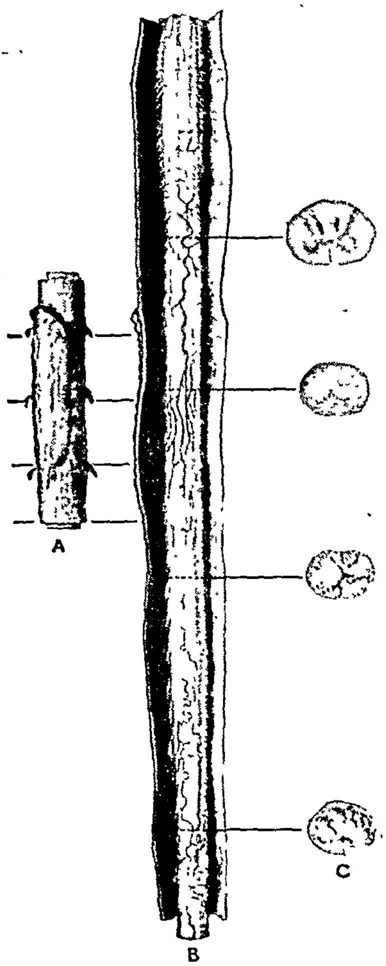

Fig. 7 (case 3).—*A*, segment of cord at the first, second and third thoracic levels showing posterior view of the organizing extradural [illegible] aspect of the [illegible] congestion, [illegible] cross sections of cord showing cavitation, softening (stippled) and hemorrhage (black).

In case 2 there was a localized cerebellar pressure cone with actual contusion of the protruding tips of the cerebellar tonsils and without general cerebral edema. Whether or not extension and flexion of the head was the mode of initial injury, it is believed that it played a role in the production of the changes found at necropsy. After edema of the cerebellum and brain stem had once been initiated, further extension and flexion could exert a kneading action that would aggravate the traumatic changes and, if continued, establish a vicious cycle. That there is a delicate balance between a swollen brain and the amount of pressure that may be applied to it by its confining case is well illustrated in case 1, in which any change in the position of the patient's head caused interference with or complete cessation of respiration.

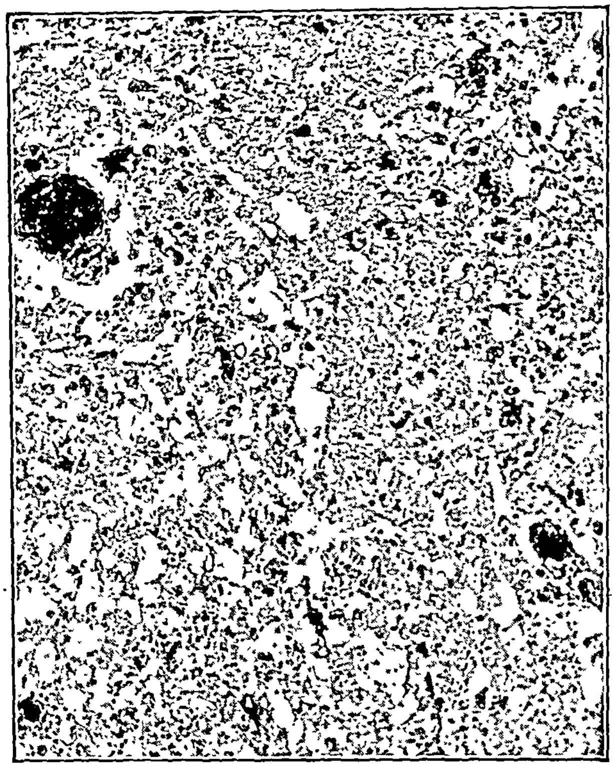

Fig. 8 (case 3).—Extensive myelomalacia with gitter cell response. Hematoxylin and eosin, × 100.

In regard to case 3, it is well known that decided cerebral and spinal injury can occur without discernible evidence of fracture or dislocation.[8] A temporary luxation of the vertebral column may occur, which quickly returns to normal; but during the brief period of displacement severe damage to the cord is produced. Lifting of heavy weights may produce spinal injury.[9] It is possible that in case 3 the patient had spinal damage due to carrying a heavy piece of steel, but in any event manipulations appear to have been ill advised and may well have aggravated his injury.

SUMMARY

Two fatal cases of cerebellar injury and 1 fatal case of spinal damage following chiropractic manipulation are described in detail.

The 2 instances of localized cerebellar trauma with associated thrombosis of basilar and cerebellar arteries appear to be unique.

A possible mechanism for the production of such injury is described.

THE ELABORATION OF HISTAMINE IN VIVO

In the Treatment of Peripheral Vascular Disorders

A Preliminary Report

ZOLTON T. WIRTSCHAFTER, M.D.
and
RUDOLPH WIDMANN, M.D.
Beverly Hills, Calif.

Recently we repeated the work of Katz,[1] who reported the intravenous administration of diethyl ether for the treatment of impending ischemic gangrene and other peripheral vascular disorders. Twelve consecutive unselected cases of definite peripheral vascular disease were treated by this method. According to the usual criteria there was improvement in 5. In 7 patients pain was not relieved throughout the twenty-four hour period, and in 8 certain unfavorable reactions were noted (table 1).

Dale and Laidlaw[2] found that ether sensitized the capillaries to the action of histamine, so that but one tenth of the dose needed in unanesthetized cats was necessary to produce "histamine shock." Histamine is known to increase the acid secretion of the gastric juice, the blood plasma receiving the resulting alkaline factors, thus leading to the so-called urinary alkaline tide. In man, histamine produces dilatation of the arterioles, venules and capillaries. Drinker[3] states that "the possibility that histamine or substances like histamine may play a normal part in bringing about capillary dilatation, and with it an increase in permeability must be considered—especially so in view of the number of organs and parts of the body from which histamine has been isolated."

TABLE 1—*Distribution, Classification and Complications of Patients Treated with Diethyl Ether*

Case	Diagnosis	Presence of Gangrene	Complications* TI	TDI	J	B	GHC†	PG	Continuance of Treatment
1. P W.	Arteriosclerosis obliterans (diabetic)	None	—	—	—	—	—	—	Yes
2 J L	Arteriosclerosis obliterans (diabetic)	None	—	—	—	—	+	—	Discontinued after 3 days
3 O S.	Arteriosclerosis obliterans (diabetic)	None	—	—	+	—	—	—	Discontinued after 6 days
4 P M	Sudden arterial occlusion	None	+	—	—	+	—	—	Discontinued after 7 days
5 G K	Arteriosclerosis obliterans (diabetic)	4th right toe	+	—	—	—	+	—	Discontinued after 11 days
6 P V	Arteriosclerosis obliterans.	None	—	—	—	—	—	—	Yes
7 F M	Arteriosclerosis obliterans.....	None	—	—	—	—	—	—	Yes
8 G S	Acroscleroderma.....	None	+	+	—	—	—	—	Yes
9 B S	Arteriosclerosis obliterans	4th right toe	—	—	—	—	—	—	Yes
10 P N	Arteriosclerosis obliterans	2d, 3d and 4th left toes	—	—	—	—	—	+	Discontinued after 22 days
11 D H	Arteriosclerosis obliterans.	None	—	+	—	—	—	—	Discontinued after 12 days
12 W S	Sudden arterial occlusion	Entire right foot	—	—	—	—	+	—	Discontinued after 2 days

* TI, thrombosis at site of injection; TDI, thrombophlebitis distant from injection site; J, jaundice; B, bradycardia; GHC, gross hematuria or appearance of urinary casts, PG, progression of gangrene.

† Always preceded by a gradual but a steady rise of diastolic blood pressure during the intravenous infusion.

In the foregoing treated series, the treatment of 7 had to be discontinued because of major complications. Two of these and, of the remaining, 4 had among other tests interval checks of their gastric acidity, urinary p_H and carbon dioxide combining power during the administration of the diethyl ether solution. Table 2 presents the results observed.

The foregoing observations in some subjects (6, 8, 9) are not consistent with the currently accepted hypothesis for the occurrence of alkaline urine and suggests the possibility of a direct action of ether on the kidney. Serum obtained from patients during treatment produced wheals and flares on intradermal injection into normal, nonallergic subjects and caused contraction of the isolated guinea pig intestine. These findings suggested a histamine release during the period of diethyl ether administration.

In 1937 Holtz[4] reported the conversion of histidine to histamine in vitro by the action of ascorbic acid. To obviate all the complications of intravenous ether, we attempted to produce this reaction in vivo. Patients were first given 500 mg. of sodium ascorbate intravenously. This was followed by the intramuscular injection of 5 cc. of a 4 per cent aqueous solution of 1(—) histidine monohydrochloride simultaneously with the subcutaneous injection of 100 mg. of sodium ascorbate. Caution was taken not to give the latter two in the same location. The subsequent regimen consisted in giving the two organic compounds in the manner described every four, six, eight or twelve hours, depending on the severity of the clinical findings. In addition, patients received 600 mg. of ascorbic acid orally daily.

To demonstrate the presence of histamine, the serum and urine of the subjects on the regimen were injected intradermally into normal nonallergic individuals and in all cases typical and decidedly strong wheals and flares were produced. Control serums and urines produced wheals and flares of a very evanescent character. It is of interest that the resulting wheals and flares in 1 (—) histidine monohydrochloride-sodium ascorbate treated patients were of greater intensity and persisted for a longer time than those produced with serum obtained from patients treated with intravenous diethyl ether. In addition, both the serum and the urine of these patients caused contraction of the isolated guinea pig intestine. All but 1 of the individuals under this regimen (a patient with known gastric ulcer) showed an absence of free hydrochloric acid in the fasting specimen prior to treatment. Following the institution of therapy, the majority revealed the presence of free acid in the fasting gastric contents.

Eleven consecutive cases of definite peripheral vascular disease seen in the Peripheral Vascular Disease Clinic at the Wadsworth General Hospital, Veterans Administration, Los Angeles, comprise the subject of

this preliminary report. All of these patients have up to the date of this report responded favorably to the therapy described and have not required amputations. The relief of intractable pain has been dramatic in the persons afflicted with it. It has occurred within six hours to three days after the institution of treatment.

Patients with gangrene, regardless of the cause, have responded most quickly; all have described a sensation of increased warmth in the affected limbs. This increase in temperature has been readily observed on examination. Extremities exhibiting black, shriveled, hard, mummified toes have shown areas of rubor in the affected parts forty-eight hours after the institution of therapy. In 1 case, that of a sudden arterial occlusion, exhibiting a black, hard, contracted, mummified foot with a definite line of demarcation at the ankle, areas of rubor appeared on the dorsum of the midfoot, the instep and the dorsal aspect of the first and second toes thirty-six hours after treatment was begun. Within two weeks the areas showing gangrene softened, filled out and began to desquamate the superficial, necrotic skin and to lighten in color. A return of function gradually appeared, though sensation has been slow in returning. All cases of gangrene exhibited a sharp, definite line of demarcation prior to treatment, though the surrounding areas were usually much inflamed. The regimen has caused the latter inflammation to subside and halted the progression of gangrene.

TABLE 2.—*Results Observed*

Case	Increase in Gastric Acidity: Free Hydrochloric Acid Only	Alkaline Tide	Carbon Dioxide Combining Power
6	None	+	Fall
7	None	+	Rise
8	+	+	Fall
9	+	+	Fall
10	+	—	Rise
12	+	+	Not tested

In the two instances of thromboangiitis obliterans studied, the response was rapid. The relief of pain, the sensation of warmth and an increase in temperature of the affected extremities were again observed.

The patients with arteriosclerosis obliterans without gangrene, and the remaining cases of sudden arterial occlusion responded similarly. The time required for the response was approximately twice that recorded.

We believe that the parenteral administration of 1(—) histidine monohydrochloride-sodium ascorbate is worthy of investigation, not only in peripheral vascular disease as such, but whenever the capillary loop is impaired and also when a collateral circulation is imperative for the repair of or reversal of the pathologic process. With such an end in view, the application of this regimen is now under investigation in this institution in coronary artery disease, angina pectoris, hypertension, glomerular nephritis, mesenteric thromboses, cerebral vascular accidents, Parkinson's disease, multiple sclerosis, thrombosis of the central retinal vein, Ménière's disease, migraine and eclampsia.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association and Hygeia, the Health Magazine
Chicago

(Continued from page 539)

(NOTE.—*Following is the seventeenth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 17. *By Leaps and Bounds*

1902-1904

When Dr. Culbertson was editor, he had called to assist him a young relative by marriage named Will C. Braun. With the retirement of Dr. Culbertson, Mr. Braun remained as advertising clerk with a salary in 1898 of $1,500 a year. The value of the services of Mr. Braun, who advanced gradually to the position of Advertising and Circulation Manager and then in 1924 to the position of Business Manager of the American Medical Association, cannot be overestimated. He grew with the Association. At the time of his retirement in 1946 he had seen the annual income from advertising increase from under $10,000 a year in 1898 to $1,750,000 in 1946.

With the incumbency of Dr. George H. Simmons as editor, Will Braun became the editorial right-hand. Many of the most significant steps taken by the Association in the development of the periodicals, the exhibits at the annual sessions, the organization of the printing department and the headquarters office may be credited to his canny intelligence.

When the committee of three, headed by J. N. McCormack and including Drs. P. Maxwell Foshay and George H. Simmons, was assigned the task of reorganizing the American Medical Association, they met frequently in the Old Grand Hotel in Cincinnati with Dr. Charles A. L. Reed, who was then President of the American Medical Association. Cincinnati was chosen because it was one night's run for each of the other members from Chicago, Louisville and Cleveland. The drive of Dr. Simmons was tremendous; he kept the other two members of the committee constantly on their toes. From each of their meetings McCormack and Foshay returned home with a mass of notes, suggestions, emendations and other material over which they would work until the time of the next meeting.

At the meeting in St. Paul in 1901, as has already been mentioned, the general principles and policies outlined in the Constitution and By-Laws were presented and almost immediately adopted. Previous to the meeting the committee had prepared a preliminary report which had been serially published in THE JOURNAL. This preliminary report follows in condensed form; the entire present structure of the American Medical Association is built according to this plan:

THE HOUSE OF DELEGATES

The committee proposed that a business section should be constituted, to be known as the House of Delegates, which should proportionately represent the state societies in accordance with their numerical strength and with the addition as directly representative of the scientific work of the Association of one delegate from each section. It was suggested that the ratio of representation be fixed at one delegate to every 500 members. Later plans were established for reapportionment at regular intervals to meet the tremendous growth in membership and thus to avoid an overwhelming number of delegates in the representative body. The organizational committee indicated that opportunity would be afforded to every state to be heard in full and that there would be free debate. The states near the place of meeting would no longer wield a preponderating influence. The House of Delegates could work without interfering with the scientific work of the Association. The committee attempted to make this body truly representative, to provide against political combinations, against perpetuation in office, and against self election to office.

In order to elaborate a complete and effective scheme for uniting the medical profession, the committee suggested plans for the uniform organization of both state and county medical societies as being directly subsidiary to the plan outlined for the Association itself. The committee was convinced that its plan would weld the profession of the entire country into a compact organism whose power to influence public sentiment would be almost unlimited and "whose requests for desirable legislation [would] everywhere be met with that respect which the politician always has for organized votes."

Many of the fundamental changes incorporated in the original Constitution and By-Laws have remained intact since the day when this enlightened group prepared them. With the presentation, they offered an argument in behalf of the proposals which was so convincing that hardly a voice was raised against it. Nevertheless the committee pointed out that a similar committee had been established at the meeting of the American Medical Association in Chicago in 1887 by Dr. N. S. Davis and that the plan then proposed by Dr. N. S. Davis was just about the same plan that they were now proposing.

The committee clearly intended that the House of Delegates would be to all intents and purposes the legislative body of the Association. It elects all the officers, it has control of the affairs of the Association, it expresses in its resolutions the desires of the profession of the country in regard to business and legislative affairs. It is truly a confederation of the state societies of the country, which, in turn, are confederations of the local societies in the states.

The previous experiences in the representative body of the Association led the committee to the belief that political considerations must, as far as possible, be eliminated from the deliberations of the House of Delegates. It therefore wrote into the By-Laws a decision that "no member of the House of Delegates shall be eligible to any office in the Association." It was believed that by this provision medical politics would be reduced to a minimum.

The committee pointed out that the Board of Trustees would have control of the finances of the Association and would be considered officers of the Association. It was the desire that at least six of the nine trustees could be independent of the existing House of Delegates and be in a position to act independently as a protection should that body in any year recommend some extraordinary expenditure.

With remarkable foresight the committee suggested in those tender days that the secretary could be the editor of the Association and it said "While it is better under present conditions for several reasons that the editor and secretary be one, the time may come in the development of the work of the Association that the duties should be separated, and hence it is thought best to incorporate the matter in the Constitution as above."

The committee recommended also that all officers be ex officio members of the House of Delegates but none of them should have the right to vote except the President, and he only in case of a tie.

As the years have passed the wisdom of this group becomes increasingly apparent. It planned well. To its planning much of the great growth and power of the organization as it exists today must be accredited.

By 1906 the mechanism was functioning smoothly. By that time the Association had 60,000 members instead of the 11,000 members at the time when the new Constitution and By-Laws were adopted.

A SPEAKER FOR THE HOUSE OF DELEGATES

The committee on reorganization was even convinced unanimously that the House of Delegates should have its own chairman, one who would be selected for his ability to preside rather than for his scientific achievements or his popularity. It was felt that the office should be more or less permanent, since the man selected as speaker of the House of Delegates would be more likely to master parliamentary rules than would be the case if he were to preside for only one year. Many of the matters that arose in the House of Delegates were considered from year to year. A more or less permanent presiding officer would have knowledge of such matters. When it came to presenting the Constitution and By-Laws to the House of Delegates, however, the committee said that this question was too delicate and that it ought to be left to the members of the House to decide for themselves. Nevertheless one member of the Board of Trustees—Dr. Happel—felt that there should be a chairman or speaker for the House of Delegates and he introduced at a later date an amendment to the By-Laws to provide for this office. The introduction of the amendment caused resentment, and the chairman of the Board of Trustees was hissed. The proposal was regarded as an insult to the President of the Association, who was then presiding. In 1916 a By-Law was passed creating a chairman of the House of Delegates and in 1918 the word "chairman" was changed to "speaker."

The committee also failed to have the courage to eliminate some of the extra vice presidents; the Association continued for a number of years to have four vice presidents. The nomination of these four was always a considerable mental strain on the members of the House of Delegates. Finally in 1920 a new By-Law provided that there be only one vice president.

There were other minor incongruities in the By-Laws but over the years these were gradually eliminated. In fact, they continue to be eliminated, since a new revision of the By-Laws is contemplated for 1947.

PULLMAN CARS

The state of medical science in 1901 was not amazingly different from the medical science of the last ten years of the previous century. Among other things, pullman cars had come into use. Dr. J. N. Hurty, then health officer of the state of Indiana, had sent a letter to the American Medical Association for improved sanitation for pullman cars. He recommended the installation of a little basin and fountain so that people could wash their teeth without using the wash basin for that purpose. He recommended that the blankets be white, so that the users of the bed could have some personal knowledge of their cleanliness.

DEATH OF PRESIDENT MC KINLEY

THE JOURNAL had shown great concern because the physicians who had taken care of President McKinley at the time of his assassination had never been paid for their services and had not rendered any bills. The editor felt that Congress should make some sort of appropriation for them.

MEDICAL ABSTRACTS

Some of the Eastern periodicals were criticizing the quality of the abstracts in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION although these were far superior to those published in any other periodical. The editor called attention to the fact that he had not created the department of abstracts but that these had first been created by the *Münchener medizinische Wochenschrift* and that it had been the policy of the editor to make them better and better all the time.

WOMEN PHYSICIANS

Strangely, the editor of THE JOURNAL, harking back to the past, still felt that women could not hold much of a place in medical practice. He said "The whole question of woman's place in medicine hinges on the fact that, when a critical case demands independent action and fearless judgment, man's success depends on his virile courage, which the normal woman does not have nor is expected to have."

THE BOARD OF TRUSTEES

The Board of Trustees of the American Medical Association had been meeting regularly in the Grand Pacific Hotel in Chicago and again at the annual session of the Association. The minutes were kept by the secretary in longhand. The editor and the advertising manager (to which position Mr. Will C. Braun had now been promoted) were being employed year by year. The Association was purchasing linotype machines and a small press. The secretary was authorized to employ stenographers to report the meetings of the Association and to furnish blank forms for the use of officers of the sections.

By 1901 the new editor was beginning to have trouble with some of the advertisements. For instance, the California Fig and Syrup Company objected to being barred from THE JOURNAL; it was finally decided that the advertisements of the California Fig and Syrup Company be accepted provided the proprietor agree to conform with the rules and that the editor was satisfied that the company was not advertising in the lay press.

In the Board of Trustees meetings in the Grand Pacific Hotel apparently not all was salubrious. For instance, observe this statement from the minutes:

> After a general discussion the motion was withdrawn and notwithstanding the persistant [sic] and annoying clammer [sic] and protestations from a subordinate of the hotel for the possession of our present meeting room, for the use of some itinerant dinner party, it was decided to hold the fort, so to speak, and continue the deliberations until the business was finished.

Interesting also is a little note indicating that before the coming of Dr. George H. Simmons the financial affairs of the Association were being somewhat imperfectly administered.

> It was stated that no satisfactory report had been received in the matter of old checks, postal notes and money orders, reported some time ago to have been found mislaid about the office, and that recently some new ones had been discovered. Dr. Happel moved, seconded by Dr. Montgomery, that all such checks and postal notes be sent to the Finance Committee, and that all Post Office money orders be sent to Dr. Johnson at Washington, D. C., for collection, and the Editor be, and he is hereby directed, to furnish all information concerning the above to the members named.

NEW MACHINERY

By 1901 Dr. Simmons reported that he had bought a small press and had put individual motors on the folder, two small presses, and the stitcher, which relieved the strain on the large motor and facilitated the work. He reported that the circulation was steadily climbing each month and that he could truthfully say that THE JOURNAL had the largest circulation of any medical journal in the world. He was then printing 25,000 copies weekly. It was becoming obvious that THE JOURNAL would have to obtain its own quarters.

RESPONSIBILITY OF THE BOARD

The change in the Constitution and By-Laws raised legal questions as to the responsibilities and authority of the Board of Trustees as compared with the incorporated association. It was felt that it would be necessary to obtain legal advice as to the exact legal status of the organization—a question which was to plague the responsible authorities for a good many years to come.

One action taken by the Board requested the secretary-editor to print a complete list of men who had held offices in the Association either in the House of Delegates or in the sections, so that there might be equitable distribution of honors in the future.

Several members of the Board of Trustees began to be disturbed over their *financial responsibilities. It* was pointed out that the salary of the editor represented the interest of 6 per cent on $100,000 and that there ought to be a business committee of the board which would take full responsibility for the finances of the Association. This arrangement has been of the greatest possible value to the American Medical Association since that time. To the finance committees of the Board of Trustees must be given much of the credit for the favorable financial position of the Association as the years have passed.

TIGHT FINANCING

The Committee on Reorganization had been voted $400 for its expenses, but the total bills represented $416.89. This gave great concern to the Board of Trustees, which eventually decided to give $400 to the chairman and let him argue it out with the other two members.

1902

SARATOGA SPRINGS, N. Y.

In 1902 the Board of Trustees moved its meetings to the Sherman House, presumably because of the "clammer" in the Grand Pacific Hotel. When in that year the Board held its first meeting, the attorney who had been called into consultation to report on the legal status of the incorporation of the Association indicated that there were apparently two organizations in the same concern: the Board of Trustees, with one set of officers, and the American Medical Association and the House of Delegates, with their sets of officers; all of this taken together was not in accord with the corporation laws of the state of Illinois. The legal opinion was profound and the lawyer was willing to suggest a technic whereby an incorporation could be completed with just one corporate body with one president and one secretary. The Board of Trustees directed the attorney to prepare the necessary papers, make the necessary changes and cooperate with the Committee on Organization, to which the By-Laws as adopted had been recommitted with authority to make verbal changes.

MORE ABOUT ADVERTISING

Again there was a considerable discussion over the advertisements of the California Fig Syrup Company, and the representative of that agency agreed to stop advertising it in the lay press. Now came another step in the cleaning of the advertising; a rule was adopted that rules governing advertisement of internal remedies should apply also to the advertisement of external remedies. There were disturbances over the advertisements of Battle & Company's Papine. The editor was authorized by the Board of Trustees to edit the various advertisements with a view to keeping out objectional expressions regarding the efficiency of the products.

THE FIRST HOME

Dr. E. Fletcher Ingals, as resident trustee, had been looking into the possible purchase of property for the Association. He recommended a space on the northeast corner of Indiana and Dearborn streets being known as Nos. 95 to 103 on Dearborn Street and measuring approximately 80 by 100 feet. The canny members of the board used part of the buildings on this property and rented the rest, thus receiving enough money out of the rentals to carry a considerable portion of their expenses. Arrangements were made to look further into the purchase of property. Finally a resolution was passed by the Board that the American Medical Association have a flag which should be known as the flag of the American Medical Association and fly over the headquarters whenever the board was meeting. The services of Dr. E. Fletcher Ingals in the development of the first headquarters building and in its equipment have never been suitably recognized by the Association. To him must be given most of the credit for the purchase of the original property and the preparation of the plans for the first building.

The first meeting of the American Medical Association with its new House of Delegates was held in 1902. The transition, as has been pointed out by Dr. Simmons, was exceedingly smooth. The meeting was held in Saratoga Springs, N. Y., early in June.

Following his resolution to the House of Delegates, Dr. H. L. E. Johnson of Washington, D. C., presented a beautiful banner to the Association. Excellent addresses were made to the House by the speaker of the New York state assembly and by Senator Brackett of New York. The technic for the establishment of reference committees of the House of Delegates was not yet perfected; on the first day of the session a business committee was set up to consist of five members to which would be referred all resolutions after being read.

The President, Dr. Wyeth, suggested an organizer who should act as a national organizer of the profession and who could visit states or territories where as yet medical organizations and society work were practically neglected. This business committee was given the address of the President of the Association and also all the recommendations that he had made.

As secretary of the Association, Dr. George H. Simmons read an extensive report in which he indicated that the same committee that had developed the reorganization had been requested by the President to formulate a Constitution and By-Laws for the state medical societies. This had been done and several state medical societies had already adopted the uniform Constitution and By-Laws. Dr. Simmons urged that all members who were not affiliated with local and state societies be dropped from membership in the Association and that the new Constitution and By-Laws be rigidly enforced. This address was also referred to the business committee.

Then the Board of Trustees reported the great improvement in the affairs of the Association that had resulted from the new methods of organization. It was a little apologetic about the advertising. "To the ordinary JOURNAL reader, it would appear to be an easy matter to lay down an inflexible rule by which the advertising department of any publication should be governed—that this should be like the laws of the Medes and Persians—but when brought face to face with many propositions, it is found to be a very difficult matter to decide what to do in each individual case. The Trustees are endeavoring to eliminate from the pages of THE JOURNAL all advertising that could be considered objectionable from an ethical standpoint."

The trustees were concerned with the overwhelming number of papers for the various sections and the difficulties of providing adequate publication. Finally they reported to the House of Delegates their action in purchasing property for the Association, and their report also was referred to the business committee.

THE PRINCIPLES OF ETHICS

Next came one of the most important actions taken by the Association. It resulted from a resolution introduced by Dr. E. Eliot Harris of New York. He said:

> For more than a year some of the members of the council of the New York State Medical Association have been engaged in a critical examination of the ethical part of the laws of the American Medical Association, resulting in the preparation of a revision of the Code of Medical Ethics. This revision has been approved by the council of the New York State Medical Association, and the delegates have been instructed to present it to the House of Delegates at this session.
>
> *Resolved,* That the President appoint a committee of five to examine and report for final action at the annual session in 1903 the proposed revised code of medical ethics which is herewith submitted in writing;
>
> *Resolved,* That the proposed revised code of medical ethics be published in the Association's Journal three times before the meeting in 1903.

This was accompanied with the complete text of the new Principles of Ethics. These resolutions were referred to a special committee to be appointed by the President. The President appointed Drs. E. Eliot Harris of New York, William H. Welch of Baltimore, T. J. Happel of Tennessee, Nicholas Senn of Chicago and Joseph D. Bryant of New York.

REFERENCE COMMITTEES

Now the business committee on which had been wished the analysis of all the recommendations of the President, the Board and the Secretary and all of the new business, came back with a report that there be appointed instead a series of committees including one on sections and section work, one on revision of the list of members, one on finance, one on the relationship of dentists and pharmacists, one on organization, and one on transportation and place of meeting. This was adopted; it constituted the first step toward the establishment of suitable reference committees for the consideration of the vast business, which comes before each meeting of the House of Delegates of the American Medical Association. The committee recommended the apportioning of all the business that had been referred to them to these various committees.

REORGANIZATION

The committee on organization report was presented by Dr. P. Maxwell Foshay, who submitted a copy of the new Constitution and By-Laws as well as the constitutions and by-laws developed for the individual states. This committee also recommended that a national organizer be employed to assist in organizing and developing the medical societies of the country. The report of this committee was adopted; later an organizer was employed.

CONFERENCE ON LEGISLATION

Another important resolution introduced by the committee on legislation called for an annual conference on legislation affecting the medical profession to be held in Washington and to include representatives of the national organization as well as representatives of the individual states.

ORIGINS OF TWO COUNCILS

The business committee in a later report recommended the establishment of two additional standing committees to be appointed by the President of the Association. These were a committee on public health and a committee on medical education. From these groups came eventually the Council on Health and Public Instruction and the Council on Medical Education and Hospitals.

THE NATIONAL EXAMINING BOARD

At this time also came the proposal for a voluntary national examining board, an idea which had apparently originated with Dr. William L. Rodman of Philadelphia. The proposal was opposed by the confederation of Medical Examining and Licensing Boards.

DIVISION OF FEES

On the final day of the session a resolution was adopted against the division of fees, to the effect that any member detected in such misconduct be expelled from his county medical society.

SOLICITATION OF VOTES FOR OFFICE

Another resolution adopted by the House of Delegates of the American Medical Association in 1902 declared that *the solicitation of votes for office is not in keeping with the dignity of the medical profession nor in harmony with the spirit of this Association and that such solicitation shall be considered a disqualification for the election to any office in the gift of the Association.* The resolution then passed has never been repealed. Later the Judicial Council declared that it was also wholly inefficient in preventing the abuse it sought to control.

DR. FRANK BILLINGS BECOMES PRESIDENT

At this session of the American Medical Association, Dr. Frank Billings was elected president. He was from that time on to be one of the most important officers in the building of the Association. Indeed to him must be credited largely the making of peace between the two medical societies in the state of New York, thus giving the Association new strength and more power for the future.

QUERIES AND MINOR NOTES

At the meeting of the Board of Trustees of the American Medical Association held in July 1902, one of the trustees suggested to the editor the desirability of a section of The Journal to be devoted to questions and answers. This section of The Journal was carried on for some twenty years with a few answers per week. For the last twenty years it has developed into one of the most significant portions of The Journal of the American Medical Association. This department now requires the services of several workers in the headquarters office and represents annually consultations with 400 or 500 experts who supply the replies. The answers are paid for at a space rate, which in no way compensates the author of the answer for the knowledge and investigation required but which represents an expenditure of thousands of dollars each year—indeed often equal to the entire budget of The Journal for the first few years of the present century.

1903

NEW ORLEANS

The report of the Board of Trustees for 1903 indicates that it had been especially active in straightening out the matter of the incorporation. The editor was being overwhelmed with work and was therefore authorized to secure the services of Dr. J. N. McCormack of Kentucky as a traveling organizer. The board described the manner in which it had purchased the property and the necessary equipment for the headquarters office.

The editor presented the names of half a dozen "patent" medicines which were accepted by other periodicals but the Board of Trustees was firm in its insistence that these not be accepted to the pages of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. The Board of Trustees presented in toto the complete discussions relative to the articles of incorporation. There had been a considerable movement to cause the Association to incorporate in a national corporation under the laws of the District of Columbia. The attorneys did not recommend such an action.

The traveling organizer, Dr. J. N. McCormack, had visited Wisconsin, Florida, Mississippi, Texas and Arkansas, and Dr. Simmons himself had gone to Missouri. Their travels met everywhere with success; the membership of the Association had increased by three times; it was decided to continue these efforts.

The committee on the Rush monument, through the work of Dr. Frank Billings, had now assembled more than $15,000. It was decided to proceed with the setting up of the monument, and the Board of Trustees appropriated $500 to bear the expenses of the dedication.

FOURTH OF JULY ACCIDENTS

The quality of American medical literature had begun to show definite improvement. The papers in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION were of a distinctly higher order than in the previous decade. About this time the editorials began to call attention to the unnecessary injuries resulting from the celebration of the Fourth of July. Eventually THE JOURNAL developed a campaign which only late in 1940 began to have an appreciable effect. Today most of the states in the United States, as a result of the campaign initiated by THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in 1903, have laws regulating the use of fireworks in celebration of the Fourth of July. While the number of injuries and particularly the number of cases of tetanus have greatly decreased, there are still some states which need to take definite action to *diminish these casualties.*

CAMPAIGNS

As an example, however, of the manner in which THE JOURNAL had begun to carry on a variety of campaigns, we must take into account the campaign against excessive injuries on the Fourth of July, the campaign for improvement of medical education demonstrated by publication in 1903 of the third annual educational number, and the campaign for better organization of medical societies indicated by the great advancement in county and state organizations. Moreover, the Association began to set aside a small sum of money to be devoted to grants for research. In an issue for 1903 appears the first paper published by a grantee.

In 1903 at New Orleans, the House of Delegates was greeted with floods of oratory by the mayor, a representative of the governor and a representative of the local bar association. No one better could have been chosen to respond to these addresses than the first vice president, Dr. J. A. Witherspoon of Nashville, Tenn., who later became President of the Association. His address was punctuated with "applause" and "laughter" in many parenthetical inserts that would have gladdened the hearts of such eminent speakers as Chauncey Depew and Joseph Choate. The concentrated attack on medical educational problems was featured by the address of President Frank Billings on "Medical Education in the United States."

The Association was presented with portraits of previous Presidents Drs. T. G. Richardson and Hunter McGuire.

In response to a resolution adopted the previous year, all business introduced was referred to the business committee without debate.

The committee on Scientific Research had selected four grantees who were investigating such subjects as the blastomycotic infections, streptococcic infections, malaria and the secretion of sweat.

More significant than the address by President Frank Billings on medical education was his message to the House of Delegates. By 1903 eighteen states had been completely organized in accordance with the plan of the American Medical Association. Dr. Billings recommended the continued employment of Dr. J. N. McCormack as official organizer. He was able to report that sufficient funds had been collected to construct the Rush monument and to promise its dedication before the end of 1903. A suggestion had been made for the establishment of a national bureau of medicines and foods, and a provisional committee had been established to consider this possibility. Out of these suggestions came the Council on Pharmacy and Chemistry.

The American Medical Association was also urged to prepare a memorial for Major Walter Reed, whose fundamental investigations of yellow fever made his name one of the greatest in the history of American medicine.

The business committee which acted as the sole reference committee for this session was concerned with the question of national incorporation for the American Medical Association. The subject was continued because it did not seem possible to make any definite recommendation.

Dr. Arthur Dean Bevan as chairman of the Committee on Medical Education made an extended report at this session which ended with the recommendation that a committee on education be established with a full time salaried assistant secretary and that they have their headquarters in the office of the American Medical Association. This was the origin of the Council on Medical Education and Hospitals.

An enlarged committee was set up to make a final revision of the Principles of Ethics, with representatives from each state on the committee. The President appointed such a committee.

The move to establish the national bureau of medicines and foods was not successful because the business committee rejected its suggestions. There was much discussion, in which Dr. Philip Mills-Jones of California led the movement in favor of such a bureau. Eventually it was referred back to the original committee.

THE REVISED PRINCIPLES OF ETHICS

On the fourth day of the meeting the enlarged committee on a revised Code of Ethics was called for a report. The committee included Dr. E. Eliot Harris, William H. Welch, T. J. Happel and Joseph D. Bryant. Their complete report as it had been worked out with the enlarged committee on the previous evening was read and on motion by E. Eliot Harris, seconded by Charles A. L. Reed of Cincinnati, the revised Principles of Ethics were unanimously adopted. The adoption of these new Principles of Ethics put an end to the controversy in New York, which had been for so many years the basis of contention. Once these new Principles of Ethics were adopted, the President of the Association, Dr. Frank Billings, and the organizer, Dr. J. N. McCormack, through meetings with representative physicians of the two groups in New York, brought about an amalgamation and the ultimate establishment of a single society in that state.

I am indebted to Dr. C. H. Bunting of Hamden, Conn., for this story as to how the revised Principles of Ethics were adopted at the New Orleans session in 1903. The committee of four already mentioned had developed a revision, to which, however, one of the members dissented. That member came to Dr. William H. Welch late in the afternoon before the House of Delegates was to meet and expressed his dissatisfaction with the committee report. Dr. Welch then agreed with him. After the motion to appoint a committee of representatives from the individual states. Dr. Welch retired to his room, took off his coat and, laying out the necessary number of long black cigars, went to work and wrote out in longhand the entire code. The committee got the code set in type and printed that night and a copy was on the desk of each delegate in the morning. As the delegates came into the meeting, Dr. Welch stood in back of the hall greeting them and telling them how much better he thought the minority report of the committee was than the original majority report. According to Dr. William Sidney Thayer, it was this lobbying of Dr. Welch for his own handiwork that resulted in the eventual unanimous adoption of the report on the Principles of Ethics.

ANOTHER STEP TOWARD THE COUNCIL ON PHARMACY AND CHEMISTRY

Later in the session Dr. Ellis of California presented a report for the provisional committee on the establishment of a national bureau of medicines and foods. That suggestion had first been made by Dr. F. E. Stewart at the session of the American Medical Association held in 1881. Dr. Ellis proposed that a national organization be formed with representatives of the American Medical Association and of the American Pharmaceutical Association to examine and analyze new remedies and to make certain that labels were truthful and that claims were warranted. The proposal was referred back to the business committee, which now recommended that this committee confer with the American Pharmaceutical Association and with the authorities of the United States and report at the next session.

BIRTH OF "TONICS AND SEDATIVES"

On Aug. 15, 1903 THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION published for the first time a column immediately following the editorial section with the heading "Clippings from Lay Exchanges." This was a column of peculiar errors made by the press in discussing medical subjects. It was to appear from time to time in the reading pages and then gradually shifted toward the advertising section of THE JOURNAL. Eventually it was to become the Tonics and Sedatives department, a section of medical humor which has come to be recognized as a unique feature of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Toward the end of the New Orleans session of 1903 the business committee which had been charged with passing on most of the active functions of the Association uttered a word of warning on what it regarded as excessive legislation. "In the past," it said, "when so little could be done, sufficient was accomplished from year to year to keep the Association abreast of the development of the profession. At present we are threatened with just the opposite danger, namely, legislation on a great variety of topics, in which the energy of the Association will be dissipated and very little accomplished. It seems to your committee that the organization of the profession, the strengthening of THE JOURNAL and the welding of the profession into a unit are subjects that will profitably occupy the energies of this House for some years to come."

THE NATIONAL CHARTER

As the year went on there continued to be agitation for the securing of a national charter for the Association, and there were many who still believed that incorporation with a national charter would be desirable. In the meantime the former Committee on Constitution and By-Laws had been changed to a new committee with Dr. M. L. Harris of Chicago as chairman. The report of this new committee was adopted so that the Association had a new Constitution and By-Laws which, with minor modifications, prevails to this time.

VENEREAL DISEASE

The American Medical Association had developed a powerful committee on the prevalence of venereal diseases. This committee presented an extensive report on the prevalence of such diseases. This committee cooperated with other agencies in endeavoring to work up a plan for the suppression of venereal disorders. Until, however, modern scientific medicine developed such aids as the Wassermann test and specific methods of treatment which would control syphilis in a reasonably short time, the outlook for stamping out venereal diseases was not particularly bright.

MORE RESOLUTIONS

Notwithstanding the warning of the business committee, resolutions were introduced to the House of Delegates on a great variety of subjects such as the purification of the mails by the elimination of advertisements for "patent" medicines, on condemning the use of wood alcohol as a dangerous poison, on the control of leprosy, on venereal diseases, on cancer, on the concept of a central committee which would act in an advisory capacity to medical periodicals in purifying their advertising, and on a great number of subjects dealing with the intimate affairs of the Association.

THE DIRECTORY

About this time also a proposal came before the House of Delegates for the publication by the American Medical Association of a directory of the medical profession. A commercial directory was being published in the United States and was supported largely by the sale of advertising space to the same type of proprietary and "patent" medicine advertising that was supporting a considerable number of medical periodicals of the nation. It was the belief of Dr. George H. Simmons and the Board of Trustees of the American Medical Association that it would be desirable to publish a directory which would be free from this unsavory commercial taint and which would be free as well from the promotional blurbs of individual physicians who were not averse to putting their best foot forward in the description of themselves and their activities which they sent to the commercial directory.

The Board of Trustees authorized the editor, Dr. George H. Simmons, to make the necessary investigations and to take the necessary steps toward the development of such a directory. This activity was eventually to bring down on the head of the editor a burst of vilification and personal attack almost unprecedented in the annals of journalism and certainly up to that time unprecedented in medical journalism.

The work of the organizer, Dr. J. N. McCormack, was being continued and insinuations began to be made against him on the charge that he was exploiting the Association. The publishers and editors of medical periodicals which were beginning to see their incomes suffer from the loss of advertising revenue joined in the chorus of attack on the editor. These attacks spread finally to direct assaults on the authority and honesty and the motivations of the members of the Board of Trustees. Moreover, the work which burdened the editor had begun to be insuperable with the growth of the Association, the establishment of a headquarters office and the ownership of a considerable amount of property, both real and mechanical.

One of the charges made against Dr. J. N. McCormack had to do with the fact that he "had been active in the politics of the Association while acting as organizer, and complaints had been presented to the Board of his active work in behalf of special candidates for Association honors."

An attempt had been made on recommendation of Dr. M. L. Harris to get the House of Delegates to select the Northern Trust Company as treasurer for the Association. With this proposal the House of Delegates disagreed and Dr. Frank Billings, a former President of the Association, was then nominated treasurer and elected by the House of Delegates. This was fortunate, because it enabled Dr. Frank Billings as treasurer to sit with the Board of Trustees for many years to come. His influence, his wisdom and his force were to be great assets to the American Medical Association during this period in its development.

1904

DEATHS OF PHYSICIANS

In the issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Jan. 9, 1904 an editorial was published on the deaths of physicians. This was apparently the first summary of the deaths of physicians —a feature that has come to be an annual feature of THE JOURNAL. It has received frequent notice in the public and medical press throughout the nation and, indeed, throughout the world. It is a natural outgrowth of the directory service and the efforts of the American Medical Association to maintain an adequate accounting of the medical profession of the nation.

ATLANTIC CITY, N. J.

The organizer, Dr. J. N. McCormack, reported that he had already visited Wisconsin, Florida, Louisiana, Mississippi, Texas and Arkansas and that Dr. Simmons had gone to Missouri. The Board of Trustees agreed to retain his services for another year.

A bill was presented to the trustees in favor of the American Printing Company for $16 for printing the Principles of Medical Ethics, which had been given to them by Dr. William H. Welch.

A suitable button was adopted as official for the American Medical Association.

At this time it was apparently the chief function of the Board to concern itself simply with expenditures and not at all with policy. Early in 1904 the Board of Trustees met in Chicago for a regular session. It was first concerned with the income of the Association from the conduct of THE JOURNAL and from other sources. During the year THE JOURNAL had been exceedingly careful in its past selection of advertisements and had rejected advertisements of:

Etna Chemical Company
Duffey Malt Whiskey Company
Mariani & Co.
Oppenheimer Institute
California Fig Syrup Company
Scott & Bowne
Charles Marchand
The Fitchmul Company
Antikamnia Chemical Company
New Animal Therapy Company
Mueller Chemical Company
The Manola Company
Micajah Company
Anasarcin Chemical Company
Osborn-Colwell Company
The Pheno-Bromate Company
New York Pharmaceutical Company
The Ringgold-Reinhart Company
C. W. Edison
Opticulin Company
Gonoseptone Company
Asthma Remedy Company
Bellbrook Sanatorium
Merrill-Hall Company
Carl Reinschild Manufacturing Company
A. S. Valentine Chemical Company

These were rejected because they were considered to be secret proprietaries, but a few others were rejected because they were advertised primarily to the public. The editor pointed out that most of these advertisements had been accepted by other medical journals in the United States.

As a result of the work of organizers and solicitors, more than 5,000 new members had joined the Association. The Association had accumulated much machinery in its own office. The profit of THE JOURNAL now had reached more than $50,000 annually.

Once the Association had begun to buy property, the trustees determined to extend their holdings; arrangements were made to buy additional houses on Indiana Street, now known as Grand Avenue.

Dr. Charles A. L. Reed as chairman of the Committee on National Legislation (to be discussed later) was given a considerable grant for the expenses of his meetings, but he was told by the board that he could have his stationery printed in the office in Chicago.

There was still much debate as to whether or not the Association ought to have a national incorporation.

PRESIDENT JOHN H. MUSSER SPEAKS

At the meeting in June 1904 in Atlantic City, Dr. John H. Musser devoted his presidential address also to medical education.

THE REFERENCE COMMITTEES

Dr. Frank Billings in an opening address to the House of Delegates presented for the first time a definite plan of organization for reference committees. He pointed out that the business in New Orleans had been greatly delayed by the fact that every proposal had to be submitted to the business committee. He proposed therefore a system of reference committees—eight in number—which prevail to this day, except that the speaker of the House of Delegates is now empowered by the House to appoint additional reference committees if there are special projects to be considered.

THE COUNCIL ON MEDICAL EDUCATION

The committee on medical education now made a definite proposal for the establishment of a Council on Medical Education to consist of five members. The history of that council and its efforts from this time on is covered in the history of the Council on Medical Education and Hospitals, which appears in this volume, written by Dr. Victor Johnson, its present secretary.

THE "PATENT" MEDICINE EVIL

The "patent" medicine evil had developed so seriously that a resolution came in by Dr. H. O. Walker of Michigan, representing the Michigan State Medical Society, requesting the Board of Trustees of the American Medical Association to provide for the analysis of medicinal products of unknown composition and undetermined effects and to publish the results in THE JOURNAL, and requesting also the establishment of a commission which would administer this function. This motion was referred to the provisional committee on establishment of a national bureau of medicines and foods. When this committee reported the results of its conferences with Dr. Harvey Wiley (then chief of the Bureau of Agriculture) and with representatives of the American Pharmaceutical Association, its report was again referred to the committee on legislation.

The report for the establishment of a national bureau failed of adoption after an extended discussion in the House of Delegates sitting as a committee of the whole. As a result, official action was not taken by the House of Delegates, but we shall see that the effects of the pressure brought about by the discussion were sufficient to cause the Board of Trustees to take an action later which resulted in the establishment of the Council on Pharmacy and Chemistry.

THE RUSH MONUMENT COMPLETED

The committee on the Rush monument reported that the monument had now been erected on the grounds of the Naval Museum of Hygiene and Medical School in Washington, D. C., and that plans for the dedication on June 11, 1904 were complete.

(To be continued)

GROUP INSURANCE AS IT AFFECTS THE PHYSICIAN

H. MAYNARD REES, M.D.
Research Director, Medical Services Insurance,
John Hancock Mutual Life Insurance Company
Boston

Group insurance is the outgrowth of the interest of American employers in the welfare and economic security of their employees. That such an interest has paid dividends in better employee relations and in greater industrial efficiency does not detract from the credit due those who developed this forward looking policy. Today labor is no less persuaded of the advantages of this type of insurance than is management. It would seem, therefore, that this institution deserves the support of all who are concerned with solving these problems.

This article proposes primarily to present group insurance to the medical profession on this premise, namely: that while it is not by any means a panacea for all the people it is a highly successful solution of the quest of the average workingman and woman for basic protection against the principal hazards of life.

Detailed examination of the principles on which group insurance is founded would be tedious and unproductive for the purposes of this presentation. All that can be attempted here is the discussion of a few of its most salient features and problems, with particular reference to their impact on the practice of medicine and related institutions in the field of health care.

In the first place, there is a three-cornered relationship between the employer, the employee and the insurance carrier which sets this type of insurance apart from the traditional two party contract. This was early recognized by government supervisory authorities with the result that special legislation now exists in many states which defines and regulates this field. Within the framework permitted by law, the private insurance companies who write this type of coverage have learned from experience what constitutes good group underwriting and have developed rules and limitations of their own. First and foremost, however, it should be remembered that legal definitions do exist and that they direct the conduct of the business.

One of the most important of these has to do with the minimum number of which a group can be composed and also with the percentage of a given group who must be enrolled. It is sometimes thoughtlessly urged that these barriers should be lowered so that the advantages of this protection may be extended indiscriminately to any collection of persons, and even to single individuals. When we consider the fact that no medical examination or history is required, it will readily be seen that if personal choice were the only determining factor in the composition of the "group," there would be a strong tendency for those who suspected that they were about to need these benefits to enroll in greater numbers. The theory of group insurance, on the contrary, is to preclude selection against the company and to rely on the adequate operation of the law of averages.

As a matter of fact, group insurance is a boon to those substandard or elderly persons who normally are to be found in every employed group, by permitting them to obtain protection at the same price as their associates. They should, however, not exceed the usual distribution of such risks in the average industrial group. When unusual circumstances, as, for instance, employment conditions during the war years, alter this normal composition, the experience is such as seriously to disturb both the basis of rates and the methods of administration.

In group insurance, risks are classified and a premium is fitted to each class which will fairly reflect the experience of that class. This is accomplished in several ways, including dividends and merit ratings, and it represents not only an answer to competition but also an incentive for prevention of the hazard and self-policing of abuses. In this latter respect it has proved effective in holding down losses with resultant savings to both the insurer and the insured.

Persons who are not members of properly constituted groups within the law are not without protection, however. A variety of policies other than group have been developed by private insurance companies, as well as by plans sponsored by hospitals and physicians, for these persons. They contain certain safeguards against exploitation of the carrier. This is typical of American enterprise in its ingenuity in meeting the needs of unstandardized minorities.

Another feature of group insurance is its remarkably low cost. There are three reasons for this which deserve at least passing notice. In the first place, as already noted, the insured group is free from adverse selection; hence the occurrence of accidents or illness will follow closely their normal incidence. Secondly, since the group represents persons and their immediate families who are for the most part in the prime of life, both morbidity and mortality rates are low.

Finally, there is the fact that administrative expense has been pared to the bone. Where solicitation does not have to be made on an individual basis, selling cost is low. Since, as a rule, no medical examination is necessary, there is an additional saving. A single policy is issued with resulting economy in accounting, premium notices and all other paper work. Finally, premium collections are not the problem that is present in the case of the individual holder of a small policy. From this will be apparent the reasons why a proper group is defined as one the members of which are employees of a common employer or, as permitted in some states, the members of which have set up an organization which can act for them in the same direct and efficient manner.

Let us now examine what the hazards are which may be covered by group insurance. The workingman's idea of health insurance is not confined to providing hospitalization and the payment of physician's bills. He believes himself also entitled to a cash payment on which his family can subsist while he, the breadwinner, is incapacitated. He has a very understandable concern over the fate of his family in the event of his sudden death or disablement from a crippling accident or illness, all hazards from which insurance can, and does, give a measure of financial relief.

How much can the average worker spare out of his wages to pay for each of these protections? The amount is determined by a number of factors, none of which is directly within the power of the physician, the hospital or the insurance company to control. It is frequently argued that many frivolous expenditures preempt a wholly disproportionate amount of the worker's budget and that he could well afford to set aside a greater sum with which to purchase protection from the serious hazards of life. No doubt in many cases this is true, but how is a wiser allocation to be brought about?

Compulsion is one method, but it has serious drawbacks. Education is sounder but slow in producing results. Industry in many instances has seen fit to contribute increasing amounts toward providing the benefits of group insurance, thereby reducing the anxiety and increasing the welfare of the employee.

The physician as the purveyor of services which are essential to the whole structure of health insurance is naturally concerned over the full use of these services and their proper remuneration. The same applies to the hospital. It is quite understandable that each of these vital services should see its own particular contribution as of paramount importance and should occasionally lose perspective in the matter of the percentage of the workingman's income which can be diverted to health insurance.

Perhaps some comfort can be derived from the knowledge that the health coverages do not present the only problem in the allocation of the insurance fund. Although the primary object is to protect the employee during the active period of his life and thereby increase his productivity, nevertheless an increasing number of employers recognize an obligation to the worker who has grown old in their service which contributions to federal Old Age and Survivors' Insurance have not wholly liquidated. Retirement plans frequently involve, in addition to a pension, the continuation of some life insurance and even of hospitalization and medical care. Since the fund earmarked for welfare is never unlimited, each decision in such a program affects the amount of premium available for every other type of coverage.

Insurance companies do their best to advise that the "group package" contain a well balanced distribution of premium income, particularly when they are consulted in time to set up an integrated program. Beyond this they cannot go; nor does it seem likely that pressure from any organization specializing in hospitalization or medical care insurance will alter the fundamentals of the situation.

However, physicians and hospitals can take certain steps to streamline their services and thereby increase their insurability. The first of these would be some standardization of charges.

There is certainly no desire on the part of insurance companies either to control or to standardize hospital care, it being the province of the physician to determine what diagnostic and therapeutic procedures are necessary to his patient. If, however, hospitals would become coinsurers to the extent of reducing their charges to an inclusive daily rate, whether this were a flat rate or one graduated downward after the first few days, they would thereby create a known quantity against which it would be much easier to insure. In most cases, both the employer and the carrier desire to provide adequate protection, but with the present prospect of unpredictable extra charges there does not appear to be any scientific way to underwrite it.

A standardized table of relationship for surgical procedures would be the first step toward the same result in the field of surgery. Such a table in itself would imply no monetary value but would fix the relative importance of different operations and would be an improvement over some of the schedules now in use.

It is doubtful that this step alone would be sufficient to protect the individual or to satisfy public opinion. It would probably have to be coupled with some obligation on the part of the medical profession to accept a scale of dollar values applicable to such a table. Because of the inertia which opposes any change from a customary standard and despite the fact that average surgical schedules now being adopted are somewhat higher than formerly, it would take time to sell management on the necessity for higher aggregate scales than those now current in different parts of this country.

If, therefore, one assumes that for the present average surgical benefits would remain about the same, the question arises as to the segment of the population from whom they should be accepted as full compensation for the services rendered. Whether or not the most equitable or the most practical solution would be a fixed income limit for the employee is a moot question. Without underestimating the difficulties involved in arriving at such limits, it is a fair statement that at present this provision is in some disrepute owing to the low ceilings set by certain medical society-sponsored plans.

It is by no means outside the realm of possibility that a pledge given by the physicians to their own society, and duly publicized, to accept such fees from persons whose only resources for all practical purposes were their insurance benefits would be acceptable to the American people in view of the high esteem in which the members of the profession are generally held. One thing, at least, is certain: this second step toward uniformity would be of inestimable assistance in bringing about more general acceptance of insurance for surgical and obstetrical care.

The objection can justly be raised that such a schedule of fees would represent a considerable sacrifice on the part of at least some surgeons. This is no new development in the practice of medicine from the time of Hippocrates to the present day. Would the physicians really want to see home, office or hospital care put on a "hard-boiled," fixed price basis? We think not. This is not a plea that physicians should permit themselves to be exploited; rather, it is the expression of a conviction that private philanthropy still has a place in the social order. It must be exercised courteously and ungrudgingly toward the person whose economic status permits of only a modest scale of insurance.

Mention was made at the beginning of this article of the self-imposed limitations required by good underwriting. They are not preconceived or hard and fast, being more in the nature of brakes on a continuous evolution. If insurance companies are cautious about entering unexplored fields, it is because of a natural desire to be very sure of the result before hazarding too large a commitment. Experimentation on a small scale, however, goes on all the time.

The problem of insuring the costs of general medical (i. e., nonsurgical) care is one such field and presents many difficulties not found in surgical expense. The greatest of these is the fact that a simple visit to the physician can by no stretch of the imagination be considered a contingency in which the insured suffers any loss or discomfort other than the payment of a small fee; nor is it outside his control. The physician, as well as the insurance carrier, is helpless to prevent an unwarranted use of his time. For every early visit that might discover some hidden condition or early treatment shorten the course of the disease, it is a fair assumption that several times as many valuable hours would be spent in futile consultation with the malingerer and the neurotic.

Restricting such coverage to hospitalized patients would not seem to be either a permanent solution or one which is in the best interests of the public health. There is a very real danger of creating an unnecessary demand for hospital beds. Such a demand interferes with the care of the truly sick.

With regard to medical care in the home and in the physician's office, safeguards for the most part have taken two forms: the restriction of coverage to the employed person who presumably would lose some of his pay, especially when the added requirement of "total disability" is stipulated, and the provision that the first few visits be paid for by the individual. More liberal provisions must wait on the development of a greater body of statistical data which is now in the process of accumulation, for until every effort has been made to reduce the risk to one susceptible of measurement with a close degree of accuracy, employers, insurance carriers and physicians alike would only be making the problem cumulative by offering an ill conceived plan of protection. The result would be a subsidy to inefficiency rather than the insuring of a risk.

In the meantime, the medical profession may be able to speed the solution of this problem by evolutionary changes in the organization of their practice. It is perhaps significant that a committee of medical men who studied the question, and whose report is the basis of an interesting experiment in community health, stated that the insuring of comprehensive medical care must be predicated on the development of group practice among doctors. It is not within the province of this article to discuss the validity of this thesis, but a broader generalization might be in order. This would be that whatever conduced to a more centralized responsibility in the treatment of illness as an entity would, of necessity, tend to regularize the average experience and hence increase its insurability.

With legislation already passed in two states and impending in several others, the question of providing cash payments in lieu of wages lost during illness becomes of prime importance. The different methods of providing such benefits are outside the scope of this discussion, but one fact emerges which challenges the medical profession to rise to even greater heights of social responsibility. No matter what system is espoused, the physician remains the final arbiter as far as eligibility of the individual is concerned. While this type of protection is justified as a means of keeping the family together in the event of true disability, there is no question but that it acts as a sore temptation to many. One hope of holding the whole system of disability benefits within bounds depends on a high order of medical certification.

The insurance company is also under heavy moral obligation. It is the custodian of a fund contributed in most cases jointly by the employer and the employee. To the extent that it is unfairly exploited by one claimant, the expense of providing benefits for all the participants will be raised. Adverse experience must be borne by the carrier in any contract year, but will certainly be taken into consideration in subsequent renewal years. Premiums must be in relationship to claims.

It is possible that in some cases too much has been expected of the physician in the way of decisions as to the competence of his patient to perform the "regular or customary duties of his occupation." While the physician must bear a peculiar responsibility in this matter, his path can be made easier by a well coordinated and smoothly functioning claims administration. Lay investigation is needed to supplement the colored history which is occasionally given to the physician by the malingerer. Examination by a disinterested colleague will frequently relieve the embarrassed family practitioner of making an adverse decision in a questionable case. Add to these the exercise of patience and tact by all concerned, and the determination of "total disability" should soon offer no more of a problem than the reporting of a communicable disease.

Insurance forms, because of their importance as a potential irritant in the relations of all insurance carriers with the physician, deserve to be treated in some detail.

In the first place, standardization of group insurance claim forms by all carriers would undoubtedly do much to mitigate the physician's very human aversion to paper work. A familiar routine loses much of its formidable aspect, requiring less time and concentration to perform. Secondly, the questions asked should be clearly stated. There should be few questions which, either by reason of their subject matter or by reason of their phrasing, cannot be answered positively and fully. If the answer can only be a matter of the physician's opinion, then the question should be so phrased.

There is, however, no excuse for the occasional attitude of physicians that certain vital information is "none of the insurance company's business." A carefully prepared form should not ask for any data which are not essential to the evaluation of the validity of the claim, and, by the same token, the patient in applying for coverage should understand that he renounces to the same extent the privileged nature of his communications to the physician. The legal status of the information to which an insurance company is entitled is clearly established. Naturally, such information will receive as confidential treatment by the company as the physician could possibly wish. Not even the diagnosis should be revealed to the insured if the physician so instructs and communicates it directly to the claims department.

Surgical nomenclature causes many headaches in claims departments. There is no standardized classification of operations in general use today, but one is available. In 1942, the American Medical Association published a revised edition of the "Standard Nomenclature of Diseases" to which was added for the first time a "Standard Nomenclature of Operations." Its universal adoption would assist both in settlement of claims and in coding for statistical purposes. Meantime, the surgeon who describes his exact procedure as well as giving it the name of some relatively obscure patron can save himself from much correspondence and his patient from delay in receiving the proper indemnity.

Finally, the physician's promptness in filling out and returning forms may make all the difference between a satisfied claimant and one who considers himself badly treated. Even if the physician feels no great urgency about collecting his fee, the average worker is disinclined to resort to his emergency fund. Hence it is a vital matter to him to receive his weekly indemnity without delay when his wages are interrupted.

The treatment of the subject of this paper has of necessity been confined to a few highlights. Some problems of the group form of insurance have been outlined, but little has been suggested as to their solution. It is felt that this latter aspect should be reserved for the committees, now functioning jointly, of the insurance industry and the American Medical Association. Representation on these committees has been assured every branch of health insurance, from the private company to the physician-sponsored plans. Their formation marks a great forward step.

The cooperation of the physicians is recognition of the importance of the insurance principle in modern economic life and of the desirability of speeding the day when every person in this country will be financially protected against the major hazards of life as fully as his circumstances permit. There is room in such a joint endeavor for every type of organization which can demonstrate its social fitness.

SUMMARY AND CONCLUSIONS

Group insurance is particularly suited to the protection of the employees of industry and their dependents from the major hazards of life. It goes beyond the question of hospitalization and physicians' bills, which contingencies must be considered in their proper relationship with such other hazards as death, loss of earnings in time of illness and retirement. Such a program requires careful allocation of the total premium available for insurance in any given case.

There are certain areas of group coverage which especially touch the practice of medicine and which present problems as yet unsolved. These include certification of disability in cash sickness compensation; improvement of schedules of surgical fees; reduction of general medical care to an insurable risk; simplification and possible standardization of claim forms.

Group insurance is continuously progressive, with active experimentation going on at all times. The solution of some of its problems must await the accumulation of experience. Others are susceptible of joint study with the medical profession.

Cooperation between the insurance carriers, including both the private companies and the plans sponsored by physicians and hospitals, and the American Medical Association gives promise of bringing about the speediest and most satisfactory coverage for all the people.

Clinical Notes, Suggestions and New Instruments

VOLVULUS OF THE ASCENDING COLON WITH REPORT OF CASE

O. CHARLES ERICKSEN, M.D.
and
RUSSELL E. GREENFIELD, M.D.
Sioux Falls, S. D.

The medical literature is studded with cases of volvulus of the colon. For examples, Perlman[1] reported 111 cases from a Russian clinic, Griffin, Bartron and Meyer[2] discussed 37 cases in patients admitted to Cook County Hospital between 1937 and 1945, and Braun and Wortman[3] listed 31 cases seen at Friedrichshain Hospital in Berlin.

When the incidence of volvulus is applied to the various regions of the colon, however, these statistics take on a new significance. The large majority involve only the sigmoid flexure. Volvulus of the cecum, on the other hand, is much less common and when it occurs it is usually associated with volvulus of the terminal ileum. Up to 1913, Bundschuh[4] could collect only 110 cases from the literature. Wolfer, Beaton and Anson[5] were able to add another 194 cases in 1942. Sweet[6] states that in a series of 520 cases of bowel obstruction reviewed by him, only 1.15 per cent were due to volvulus of the cecum.

When the ascending colon is considered, it appears to possess almost complete immunity to volvulus. Rothman, Bruckner and Zetena[7] described 1 case in 1943, but it was the only case we were able to find in recent literature. This paper will add a case to that of Rothman and his colleagues and will attempt to explain the extreme rarity of volvulus of the ascending colon by contrasting it to that of the sigmoid flexure and discussing the etiologic factors operating in the pathogenesis of volvulus in general.

The case reported by Rothman, Bruckner and Zetena had certain points of interest. The cecum of their patient was found in the left upper quadrant of the abdomen. Such extensive abnormal anatomy would indicate either a lack of fixation of the entire ascending colon with an extremely long ascending mesocolon or, more likely, a congenital maldevelopment such as that occasionally found in the newborn. Embryologically the cecum and ascending colon pass through four stages. In chronologic order they are migration, rotation, descent and, finally, fixation to the dorsal wall. It seems probable that in the case under discussion[7] the ascending colon had failed to rotate and descend; consequently, it had at no time been in a normal position. Certainly fixation had never occurred. If such a maldevelopment did exist, it is not hard to understand why the patient exhibited an acute obstructive volvulus when brought to surgery. It is really more difficult to understand how the patient could live forty-one years before the acute obstructive phase developed. In the case to be reported by us the patient did not have such a maldevelopment.

Faulty fixation of the ascending colon is a common anatomic variation. Chalfant[8] estimated that definite mobility of the right side of the colon is present in approximately 20 per cent of persons of all ages. Certainly, then, mobility alone is insufficient to cause volvulus of the ascending colon as it appears to do frequently in the sigmoid flexure. The consistently mobile small intestine is further evidence that mobility per se does not commonly cause volvulus. Apparently the mobility must be of a special type, or a second etiologic factor *must act with* the mobility, before volvulus results.

In discussing the relationship of bowel mobility to volvulus, it is readily seen that the bowel not only must be free to move from side to side but also must be free to rotate on its attachment. To encourage volvulus, the ideal attachment of the mesocolon to the dorsal wall is a fixed point rather than a line. Ascending mesocolons have a relatively long line of attachment and are rectangular in shape. Therefore even though the ascending colon is quite mobile, its mesocolon is so constructed that the mobility allowed the colon is mainly linear and not rotatory. Thus the mobility is of the wrong type and twisting is prevented. If the ascending mesocolon were fan-shaped, as is the mesosigmoid, volvulus could occur more readily.

Directly related to the anatomy of the mesentery as an etiologic factor in volvulus is the degree of bowel redundancy. If the intestinal segment is kept straight by the tension exerted on it by the immediate distal and proximal parts of the bowel, volvulus is prevented. To illustrate hypothetically: give a structure such as the esophagus a foot-long, fan-shaped mesentery and allow adequate room for mobility by removing all adjacent viscera in the thorax. The pharynx on one end and the stomach on the other would keep the esophagus stretched taut and prevent volvulus. The ascending colon tends to present a comparable picture with the cecum and hepatic flexure holding the ascending colon stretched out between them. The sigmoid colon, however, offers the opposite condition. The average adult sigmoid is 40 to 50 cm. long. It is attached through its mesentery to a line on the dorsal wall no longer than 20 to 25 cm., *leaving 20 to 30 cm. of the sigmoid free for twisting* and flexing. However, the sigmoid frequently elongates to lengths far greater than average, while the line of attachment remains constant. Fernström[9] reviewed 15 cases in which the sigmoid flexure measured between 195 and 200 cm. In such cases there is as much as 6 feet (180 cm.) of redundant bowel free to twist around the fan-shaped mesosigmoid.

Tumors, cysts, adhesions, fecoliths and foreign bodies are other organic conditions producing a diathesis to volvulus.

Mesenteric tumors, cysts and fixation bands tend to produce anatomic conditions comparable to those predisposing to volvulus that have already been mentioned. They act as a fixed point of attachment around which the loop of bowel may twist. Occasionally adhesive bands form at the base of the mesentery and then, through contraction, shorten the line of attachment and produce a fan-shaped mesocolon. Since these cysts, tumors and adhesions probably occur on both sides of the abdomen with equal frequency, they help but little in explaining the difference in incidence of volvulus of the ascending and of the descending colon.

Intracolic conditions also influence the incidence of volvulus. The contents of the ascending and of the descending colon differ greatly in physical consistency. The stool in the ascending colon is soft or liquid, while that in the descending colon is formed and often hard. This difference in bowel content may be an important cause of the higher incidence of volvulus on the left than on the right side. Bloodgood[10] and Bargen[11] agree that dilatation, thickening and elongation of the descending colon often result from the hard feces, collections of gas and defecation difficulties associated with constipation. Such does not occur in the ascending colon.

Occasionally volvulus of the intestine can be produced by a force acting directly on a loop of bowel. This force may be provided by an organ such as an ovarian tumor with a long pedicle or a hydrosalpinx or pyosalpinx which has become attached to a loop of small bowel. Torsion of these organs is a common occurrence, and when they are adherent to intestine a secondary volvulus of the intestine may be the result. This secondary volvulus of the intestine may be far more serious than the primary volvulus of the organ involved (ovary, tumor or cyst). Such secondary volvulus almost always involves the small rather than the large intestine and often results in gangrene necessitating resection.

The role of purgatives in the pathogenesis of volvulus should not be omitted. Patients who have an anatomic or organic diathesis to volvulus may be thrown into an acute attack of volvulus by the violent peristalsis produced by purgatives.

The following case illustrates how volvulus can occur in the ascending colon which had fully migrated, rotated and descended but which had not become fixed to the dorsal wall. Acting on the abnormal mobility was a tumor, which is generally conceded to be one of the rarest in the abdomen. It was a cyst in the mesentery of the hepatic flexure. Judd and Crisp[12] reported that the Mayo Clinic found only 8 mesenteric cysts in 820,000 admissions; the Massachusetts General Hospital had 6 cases between 1912 and 1929, and Los Angeles General Hospital had 1 between 1912 and 1934. Miller[13] sums up their rarity by stating that less than 400 cases had been reported to 1935.

REPORT OF CASE

History.—Mrs. O. B., a white woman aged 30, a farmer's wife, entered McKennan Hospital Oct. 26, 1945 with a chief complaint of intermittent attacks of abdominal pain. The first attack had occurred approximately six years ago, with a total of ten in the last six years. The patient stated that the pain was always located in the right hypochondrium and started suddenly without warning, lasting from two hours to two days and forcing the patient to double up. The pain tended to radiate across the epigastrium and was portrayed as sharp, cutting and burning. It was constant and not intermittent during the attack and was not associated with nausea, vomiting, anorexia or obstipation. Three months prior to her entrance to the hospital, the patient gave birth to her seventh child, after which she could feel something moving back and forth across the epigastrium. However, there was no history of colic or audible borborygmi. Stools and bowel movements were always normal during the attacks. Each attack became more severe than the preceding one, and they occurred with increasing frequency.

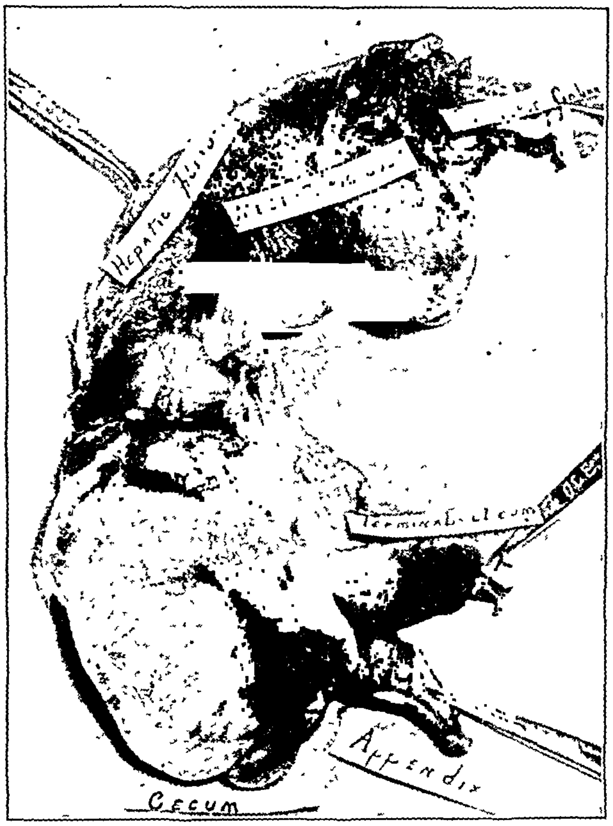
[13] Miller, L. A.: Rarity of Congenital Mesenteric Cyst, Am. J. Dis. Child. **50:** 1196-1202 (Dec.) 1935.

The past history of the patient revealed only childhood illnesses with no previous surgical operations. The family history was essentially noncontributory. Inventory of the patient's systems revealed nothing in addition to her present illness. The patient was a septipara and septigravida with all normal deliveries and no associated complications. Her menstrual history was normal in all respects except for irregular periods with intervals of five to six weeks.

Immediately prior to her entrance to the hospital, she was suddenly seized with severe pain in the right hypochondrium which was constant, doubled her up and produced extreme tenderness along the right half of the abdomen. She again had no obstipation, no vomiting, no distention and no nausea. She was unable to stand erect and experienced considerable giddiness.



Specimen removed at laparotomy.

Physical Examination.—Physical examination revealed entirely normal conditions except for the abdominal observations. When she was first seen, there was some definite tenderness in the right upper quadrant, but tumor masses could not be made out, the patient being fairly obese. Vaginal examination was entirely noncontributory. Urinalysis and examination of the blood revealed normal conditions. A roentgenogram of the gallbladder, after the gallbladder dye had been ingested, revealed a normally functioning gallbladder. After the patient had been in the hospital for two or three days, it was thought she was recovering spontaneously. However, on the third day, October 29, she experienced another attack which was more severe than any she had had previously. At this time a suggestion of a tumor mass could be felt to the right and below the umbilicus. Although a barium clysma had been planned at this time, it was decided that the patient had an acute condition requiring surgical intervention in the abdomen, and without further delay she was prepared for an abdominal laparotomy.

Surgical Operation.—Under cyclopropane anesthesia a midline suprapubic incision was made, and when the abdomen was opened blood-stained fluid was found. Exploration revealed that the liver was normal on palpation. A mass was found in the right portion of the midabdomen which was approximately the size of a medium grapefruit. In order to get a better examination, the incision was extended 2 inches (5 cm.) above the umbilicus, and the mass was delivered through the incision. The mass was found to consist of a twisted ascending colon, which had been twisted clockwise approximately 240 degrees. When this bowel was untwisted, it was found that a tumor was intimately attached to the hepatic flexure of the colon and to the medial leaf of its mesentery. Careful examination of the tumor revealed that it was a trilocular mesenteric cyst. Two of the loculated parts of the cyst were anterior and one was posterior between the leaves of the mesentery. The latter could not be seen from the front but could be palpated readily. There were several dark, ecchymotic areas on the peritoneal surface of the ascending colon, and the bowel wall was extremely congested and distended. There appeared to be thrombosis of the right colic veins. Numerous swollen glands were present in the right mesocolon. The cecum was found to be hypermobile but situated in the right lower quadrant of the abdomen and not involved in the volvulus.

A right hemicolectomy was performed with ease through the suprapubic incision because of the extreme length of the ascending mesocolon. The terminal 6 inches (15 cm.) of the ileum, the cecum, the appendix, the ascending colon and the right half of the transverse colon were removed. The terminal end of the ileum and the proximal end of the transverse colon were then closed, following which a side to side anastomosis was performed without using clamps. The entire operative procedure required sixty minutes.

The postoperative course was uneventful. The patient had a normal bowel movement on the third day, and during the postoperative course she did not at any time have diarrhea or frequent stools such as commonly occur after resection of the right half of the colon. Since her surgical operation she has enjoyed excellent health and is doing her work without complaints.

Pathologic Data.—The pathologist's report is as follows: The specimen consists of 6 inches (15 cm.) of the terminal portion of the ileum, the appendix, the cecum, the ascending colon and the right half of the transverse colon. The bowel wall of the ascending colon, and especially the hepatic flexure, is edematous, and there are numerous dark, ecchymotic areas underneath the peritoneum. The mesenteric veins are thrombosed, but branches of the right colic artery appear entirely patent. In the hepatic flexure, there is a trilocular mesenteric cyst, two in front and one situated between the leaves of the mesentery. Each of the three is approximately the size of a lemon, and their appearance is that of a simple mesenteric cyst. They contain a clear, slightly stained fluid. Microscopic examination reveals the tumor to be a true cyst, the lining of which is endothelium.

SUMMARY

1. From the data reported in the literature it is apparent that (*a*) volvulus of the sigmoid flexure is relatively common, (*b*) volvulus of the cecum is rare and (*c*) volvulus of the ascending colon is almost unknown.

2. Analysis of the anatomic and physiologic peculiarities of these three parts of the colon reveal that:

A. Various conditions predispose or directly produce volvulus. The majority of these etiologic conditions are familiar to the descending colon and foreign to the ascending colon. Thus is explained the wide difference in incidence of volvulus of these two parts of the large bowel.

B. A combination of two or more etiologic forces may be necessary before volvulus results. Considerable mobility of the ascending colon is common, but it alone does not cause volvulus. The other conditions that can team up with this mobility to produce volvulus of the ascending colon, such as those in the case reported in this paper, are infrequent.

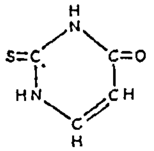
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

THIOURACIL.—2-Thiouracil.—$C_4H_4N_2OS$.—M. W. 128.15. The structural formula of thiouracil may be represented as follows:



Actions and Uses.—Thiouracil interferes with the formation of thyroxin by the thyroid gland. It is useful in the treatment of hyperthyroidism, thyrotoxicosis and thyroiditis. It is of no value and should not be used in other derangements of thyroid activity or in conditions not associated with hyperthyroidism.

Since thiouracil does not inactivate or interfere with the action of thyroxin already formed and stored in the gland, the effects of thiouracil medication do not appear until this store of thyroxin has been utilized. It may take several days to several weeks for the signs of decreased thyroid activity to become manifest, particularly if the patient has received previous iodine therapy.

Not all patients experience a permanent remission following thiouracil therapy, and the duration of treatment necessary to secure permanent relief from hyperthyroidism has not been determined. On the basis of the available information, it can be recommended only that thiouracil be used for preoperative treatment or for those patients for whom operation is contraindicated. The wisdom of depending on thiouracil as a substitute for operative procedure can be determined only by following the results of investigations carried on for longer periods.

Thiouracil produces adverse reactions in a high percentage of patients. The most frequent and severe complications of thiouracil therapy are granulocytopenia, leukopenia, drug fever and dermatitis. Jaundice, purpura and anemia have been reported following thiouracil therapy. The drug should be discontinued and appropriate therapy commenced immediately on the detection of signs of any of these complications.

Since the mild and the juvenile types of hyperthyroidism can frequently be controlled adequately by iodine therapy alone, thiouracil should not be used for these patients unless the safer form of therapy proves ineffective.

Dosage.—Initially 0.4 Gm. per day in divided doses, and after the symptoms are controlled or the basal metabolic rate is within the normal range the dose should be reduced to 0.1 or 0.2 Gm per day. *Patients should be instructed to cease medication and report to their physician immediately if any adverse symptoms such as sore throat, fever, coryza or malaise are experienced.*

Tests and Standards—

Thiouracil occurs as a crystalline powder having not more than a slight yellow tint or more than a slight odor and possessing a bitter taste. It melts about or somewhat above 300 C. It is slightly soluble in ethanol, very slightly soluble in water and in ether, and practically insoluble in chloroform and in benzene. The *p*H of a saturated aqueous solution of thiouracil is within the range 4.8-5.5.

Add 5 cc. of 50 per cent sulfuric acid to 0.1 Gm. of thiouracil in a test tube. Hold a piece of moistened lead acetate paper over the mouth of the tube and heat the mixture: a black color develops on the paper.

Slowly add bromine water to about 25 mg. of thiouracil in a test tube until a faint yellow color persists. Discharge the color with heat. Cool and add 10 cc. of saturated barium hydroxide solution: an opalescent, lavender colored precipitate develops.

Add a few drops of silver nitrate solution to 2 cc. of a saturated solution of thiouracil in ammonium hydroxide: a precipitate forms which redissolves on shaking. Add 1 cc. of silver nitrate solution: a slightly greenish gelatinous precipitate forms.

Dry 1 Gm. of thiouracil, accurately weighed, to constant weight at 100 C.: the loss in weight does not exceed 0.5 per cent.

Char about 1 Gm. of thiouracil, accurately weighed, cool, add a few drops of sulfuric acid to the cooled mass and ignite: the amount of residue is not more than 0.10 per cent.

Add 4 cc. of water and 1 cc. of silver nitrate solution to 0.5 Gm. of thiouracil in a test tube. Add 5 cc. of nitric acid and allow to stand until the reaction is complete. Expel the oxides of nitrogen by heating, dilute with 10 cc. of water and cool to room temperature: the turbidity does not exceed that of 0.1 cc. of fiftieth normal hydrochloric acid used as a control.

Heat 75 cc. of water containing 1.5 Gm. of thiouracil for ten minutes on a steam bath. Cool, filter and adjust the volume of filtrate to 75 cc. by washing the filter paper. Add 1 cc. of barium chloride test solution and 5 drops of dilute hydrochloric acid to a 50 cc. portion of the filtrate: the turbidity does not exceed that of 0.2 cc. of fiftieth normal sulfuric acid used as a control.

Dissolve 1 Gm. of thiouracil in 8 cc. of sodium hydroxide test solution, and dilute to 20 cc. with water. Add 5 drops of 10 per cent sodium sulfide solution: no more color develops than corresponds to 20 parts per million of lead (U. S. P. XII, p. 586).

Weigh accurately about 50 mg. of thiouracil and transfer to an iodine titration flask. Add .0 cc. of water, 1 cc. of normal sodium hydroxide and 50 cc. of tenth normal bromide bromate solution. Acidify with 10 cc. of hydrochloric acid, stopper, and let stand for ten minutes. Add 10 cc. of 10 per cent potassium iodide solution, stopper and seal with 5 cc. of chloroform. Let stand for five minutes and then allow the chloroform to enter the flask. Titrate with tenth normal sodium thiosulfate to the disappearance of color in the chloroform layer. Each cubic centimeter of tenth normal bromide bromate solution is equivalent to 0.001282 Gm. of thiouracil: the thiouracil content is not less than 98 per cent nor more than 102 per cent.

THIOURACIL TABLETS:

Weigh accurately twenty thiouracil tablets and grind to a fine powder. Transfer about 500 mg., accurately weighed, to a 100 cc. volumetric flask. Add 5 cc. of 10 per cent sodium hydroxide solution and dilute to volume with water. Mix thoroughly, filter and pipette 20 cc. of the filtrate into a 250 cc. iodine flask. Add 50 cc. of tenth normal bromide-bromate solution, 10 cc. of 10 per cent hydrochloric acid, stopper, shake and allow to stand for ten minutes. Add 10 cc. of 10 per cent potassium iodide solution, stopper and seal with 5 cc. of chloroform. Let stand for five minutes and then allow the chloroform to enter the flask. Titrate with tenth normal sodium thiosulfate to the disappearance of color in the chloroform layer. Each cubic centimeter of tenth normal bromide bromate solution is equivalent to 0.001282 Gm. of thiouracil: the thiouracil content is not less than 95 per cent nor more than 105 per cent of the claimed amount.

SATURDAY, MARCH 1, 1947

IODIZED SALT AND GOITER

The Council on Foods and Nutrition of the American Medical Association, some time ago, adopted a general decision on the use of iodized salt in the prevention of goiter. The Council indicated its belief that iodine is an essential chemical element for normal nutrition and that an inadequate supply of iodine in the diet tends to the development of an iodine deficiency disease known as simple goiter. In its decision the Council emphasized its point of view that this is wholly a preventive measure and is not concerned in any way with the cure of goiter. It defined an accepted iodized salt as one containing not more than 1 part of sodium iodide or the iodine equivalent of any other suitable iodine compound to 5,000 parts of salt. Iodized salt containing more than this quantity is considered a medicament, not to be advertised to the public for table or cooking uses.

At a meeting of the Council held in November 1946 the Council was informed that legislation would be introduced into the Congress designed to amend the Food, Drug and Cosmetic Act so that table salt would be required to contain an amount of iodine equivalent to that specified in the general decision. The Council, therefore, recommended to the Board of Trustees of the Association that action be taken toward giving the support of the American Medical Association to such standardization of table salt. The Board of Trustees at its meeting in December 1946 approved this action of the Council.

In an article published in the *Ladies' Home Journal* Senator Desmond of New York urged the Food and Drug Administration to standardize table salt in this manner, and Dr. P. B. Dunbar, Commissioner of Food and Drugs, rightly pointed out that the Food and Drug Administration cannot require that salt be iodized without adequate legislation. In this connection Mr. Alexander Falconer, secretary of the Salt Producers Association, said that the salt companies are willing and glad to aid by standardizing salt in the manner suggested but that it is illegal and impossible for them to agree among themselves to produce only table salt containing the requisite amount of iodide. He believes that the proper procedure would be continuous education by physicians and public health officials leading the public to use such salt.

In the midst of this drive toward aiding the prevention of simple goiter in the manner suggested comes an announcement by Dr. Isidor Greenwald of New York University College of Medicine of his belief that a deficiency of iodine is not related to the causation of simple goiter and asserting also that the giving of iodine to people in so-called goiter belts has not reduced the incidence of new goiter to zero. This extraordinary folly, unsubstantiated by anything resembling scientific evidence, has been circulated by Science Service. Moreover, one of the staff writers at Science Service has supported the statement by wide distribution in a syndicated column.

Physicians who have carefully followed the scientific literature on the subject will naturally deprecate the unfortunate publicity given to the unsubstantiated views of Dr. Greenwald. The Council on Foods and Nutrition made its decision after a careful study of the available evidence. The experiences in such states as Michigan and Ohio are sufficient to establish that the widespread use of additional iodine in the diets of growing children in areas where iodine is deficient in the soil is a most valuable technic for preventing a vast amount of unnecessary simple goiter. The fact that goiter still occurs occasionally in such areas may then be taken as evidence that standardization of table salt to contain the necessary iodine would bring about a still further reduction in the incidence of simple goiter.

PERIARTERITIS NODOSA AND HYPERSENSITIVITY

Periarteritis nodosa has generally been regarded as a rare disease, probably infectious, that almost always ends fatally and has rarely been diagnosed in vivo. Since its original description by Kussmaul and Maier in 1866 and by P. S. Meyer in 1878, who described the syndrome as a triad of chlorotic marasmus, polymyositis and polyneuritis with gastrointestinal symptoms, some 400 cases have been recorded. More recent observations suggest that the disease is not as rare as was formerly believed. With greater familiarity by the clinician its diagnosis in vivo should not present insuperable difficulties; it is not necessarily always fatal, and it probably represents an allergic reaction of the small arteries to a variety of antigens, rather than being a specific infectious disease.

The pathology of periarteritis nodosa was described by Gruber in 1926 and by Arkin[1] in 1930. Whatever the causative factor, its elective affinity for the arteries of the body is its distinguishing pathologic feature. The organs most frequently involved, according to Arkin, are the kidneys, heart, liver, muscles, peripheral nerves and the gastrointestinal tract. The process is usually widespread but may be limited to the arteries of a single system or of a single organ. The chief histologic feature is a necrotizing lesion of the arterial wall with a surrounding inflammatory reaction. The earliest changes are to be found in the media, with later involvement of the subintima or of the whole thickness of the wall. The chief secondary changes in the arteries are aneurysm formation, thrombosis and hemorrhage.

The clinical manifestations are extremely varied. More than half the cases have an acute onset, frequently with high fever, chills, a polymorphonuclear leukocytosis, occasionally eosinophilia, and manifestations of severe infection. The symptoms vary with the location of the process and the nature of the secondary changes in the vessels. Renal, cardiac, peripheral nerve and gastrointestinal symptoms are most common. The usual mode of onset noted by Spiegel[2] included severe abdominal pain associated with articular, cardiac or renal symptoms. There may be icterus, enlarged spleen and enlarged, hard lymph nodes. Hypertension, nephritis, renal insufficiency, cardiac failure, intense abdominal pain, ulceration or gangrene of the bowel, peripheral neuritis and muscular atrophy are the characteristic symptoms in advanced cases. Death is caused by renal insufficiency, cardiac failure or rupture of an aneurysm. The diagnosis is difficult except in the rare cases which exhibit the characteristic subcutaneous nodules with the characteristic histologic changes in the blood vessels.

The etiology of periarteritis nodosa has been attributed to syphilis, to a filtrable virus, to various infections, to toxic injuries and to disease of the central nervous system. Gruber was among the earliest investigators to suggest that the condition might be due to hypersensitivity. The recent observations of Rich[3] and of Rich and Gregory[4] add support to this theory. Rich found vascular lesions characteristic of periarteritis nodosa in the viscera of 5 patients who shortly before death had had hypersensitive reactions following therapeutic injections of foreign serum; in a biopsy of muscle from a patient who had a hypersensitive reaction following foreign serum and sulfonamide therapy, and in the viscera of a patient who had received prophylactic sulfonamide therapy against aspiration pneumonia. None of these patients had had any symptoms suggestive of periarteritis nodosa prior to their terminal, acute illness for which the serum or sulfonamide was administered, and the vascular lesions were fresh. Clark and Kaplan[5] observed arterial lesions of the same character as those of periarteritis nodosa in two necropsies on patients who had serum sickness shortly before death. Rich and Gregory produced typical diffuse periarteritis nodosa by establishing in rabbits a condition analogous to serum sickness in man. These experiments, as well as the clinical observations of Rich, suggest that periarteritis nodosa is one manifestation of the anaphylactic type of hypersensitivity. Acute, diffuse glomerulonephritis occurred in a number of the animals that developed a hypersensitive reaction to the foreign serum. This supports the view, in the opinion of these authors, that some cases of glomerulonephritis in man may be due to hypersensitivity. Further support is given by the observations of Reimann,[6] who found typical lesions of periarteritis nodosa in 2 cases diagnosed as trichinosis. He believes that trichinosis may be a disease with strong allergic manifestations and that it may in certain instances serve as one cause of the syndrome called periarteritis nodosa.

FREE MUSCLE MYOCARDIAL TRANSPLANTS

Experiments by O'Shaughnessy[1] and Beck[2] have shown that pedicle muscle grafts on the heart result in the creation of a significant vascular anastomosis between the two tissues. Such grafts not only bring extra blood to the heart but also serve as anastomotic channels between healthy and diseased coronary beds. Clinical applications of large pedicle muscle grafts, however, are limited because of the extensive surgical manipulation involved.

A simpler technic for the replacement of myocardial infarcts had been previously suggested by Leriche and Fontaine,[3] who recommended the use of nonpedicle or free muscle grafts. The feasibility of free muscle grafts has been recently tested by Weinstein[4] and his associates of the Laboratory of Experimental Surgery, New York University College of Medicine.

Nine dogs were anesthetized by intravenous injection of pentobarbital sodium. Positive pressure was maintained in the lungs when the thorax was opened. Free muscle grafts, rectangular and averaging 7 by 4 cm., were obtained either from the internal oblique muscle of the abdominal wall or from the vastus lateralis of the lower extremity. The graft was placed about the heart and anchored to it by means of three or four fine cotton sutures. The epicardial surface was not scarified. The pericardium was sutured over the graft, the latter being included in the suture line. The Emerson respirator was used in reestablishing voluntary respiration.

Except in cases of infection, the postoperative course was not accompanied with shock or severe disability. After a period of ten to fifteen weeks, 6 animals were killed and the cardiac transplants examined. In 3 dogs there were signs of intrapleural, pulmonary and pericardial infection. In these dogs a total absorption of the muscular elements of the graft had occurred with replacement by connective tissue.

In the 3 noninfected dogs successful takes were found. The grafts were well fixed to the myocardium with little or no mobility. Between the grafts and the myocardium there was a rich vascular network. Sections taken through the grafts showed normal muscular structure. Evidences of deleterious effects on cardiac function, extrapericardial adhesions or increased intrapericardial pressure were absent. The remaining 3 dogs are still alive and have not shown signs of postoperative infection.

Weinstein believes that this is sufficient evidence that free muscle transplants may be successfully grafted on the canine myocardium.

Current Comment

HUMAN GLANDERS

Glanders is primarily a disease of horses. The few human beings who have been victims in the past have usually been infected by contact with these animals. Apparently the only case of glanders in a human being that has occurred in the United States in recent years was reported in 1938.[1] Recently, however, Howe and Miller[2] have recorded 6 cases of human glanders within one year among a group of laboratory research workers. The causative organism, Malleomyces mallei, was not isolated in any of the cases, though all had been involved in laboratory work with this organism. In none of the cases could the incubation period be accurately determined. Incidental evidence suggests that the incubation period ranged from about ten to fourteen days. Pulmonary lesions were present in 5 of the 6 cases, which suggests that the main route of infection was through the respiratory tract. The diagnosis of glanders was based principally on a significant and sustained rise in the serum titer of agglutinins for M. mallei; this occurred in 5 of the 6 cases, and the sixth case showed a rise in titer of lesser degree. Persistent leukopenia and relative lymphocytosis were the only other striking laboratory observations. A positive reaction to the intracutaneous injection of 0.1 cc. of commercial mallein in a dilution of 1:10,000 accompanied the significant serologic response in 5 cases. In 4 of the cases the lesions observed by x-ray suggested an early stage of lung abscess, though in 1 case the x-ray film showed a diffuse lesion more similar to pneumonitis in character. The patients were treated with sulfadiazine because of the apparent efficacy of this drug when given to animals injected experimentally with M. mallei. The clinical response was not entirely clearcut in all cases, but the indications are that infection with M. mallei is amenable to treatment with sulfadiazine and that the use of this drug warrants further trial in cases of human glanders. Although this report of 6 cases deals only with laboratory infections, the evident ability of M. mallei to invade the human body suggests caution in dealing with this equine disease.

THE MEDICAL RECORD LIBRARIAN

The classification and care of medical records in hospitals and similar institutions have become increasingly important. The wide use of the Standard Nomenclature of Disease and Operations sponsored by the American Medical Association since 1937 has been a significant factor in this development. Coincidentally the functions of medical record librarians have increased in significance for hospital science. An adequate supply of trained professional medical record librarians, however, has not kept pace with the greater need for such services. As a temporary expedient a short in-service training program, financed by the National Foundation for Infantile Paralysis, has been established by the American Association of Medical Record Librarians. This program is designed to assist those who are now working in medical record libraries but who are unable to attend an approved school. This program is only a week long and cannot be compared with the training which is obtained in the regular courses, which include at least 208 hours on medical fundamentals and terminology. Physicians should appreciate the difference in training between a regular course in medical record work and the abbreviated in-service training. Record library personnel who have had only the latter lack the background of medical terminology and medical fundamentals desirable if they are to be of greatest possible assistance to the professional staff. The medical staffs, therefore, will need to spend more time in explanation of diagnostic terms and medical fundamentals with members of this group than they will with those who have had the thorough grounding furnished by approved regular schools in medical record library work.

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

(Concluded from page 555)

Saturday, December 7, Evening

SESSION FOR SECRETARIES

Dr. Douglas L. Cannon, Montgomery, Ala., *Presiding*

Dr. L. Fernald Foster, Secretary, Michigan State Medical Society, read a paper on Commercial Exhibits.

The Home Office of a State Medical Association

Mr. R. H. Graham, Executive Secretary, Oklahoma State Medical Association: I am going to take the opportunity of doing what others have done today, and that is to digress from my assigned subject. In Oklahoma we have tried to conduct the home office in the manner in which the Council has designated. I cannot comprehend how a home office can function properly outside the capital city. Fifty per cent of my time outside of the administrative duties are with some governmental agency, and I believe that a state medical association should take that into consideration. Many members do not know what exists in a home office, for they have never been there. In many instances the reason is that it has been difficult to get to that particular office. If an office can be located where it is easy to stop in, I think you will be surprised at the number of doctors that will do so.

This state association has for ten years conducted a postgraduate course in medical education which was copied somewhat after that of the state of Tennessee. We bring in an outside speaker and pay him a liberal salary. The course takes two years to conduct in forty teaching centers. It started with obstetrics, then went to pediatrics, internal medicine, general surgery and diagnosis, and it will soon start gynecology. This state medical association has about 1,500 members, and since the inception of that course there have been over 1,000 members who have enrolled and attended seven of the ten lectures. That is a home office in action.

By the same token, a county medical society decided that there might be something wrong with the malpractice insurance policies and the rates. And through their initial effort and subsequently through that of the state medical association there was employed a firm of insurance attorneys who wrote a policy. It was taken to one of the largest insurance companies who underwrote it. The rate was reduced from approximately $70 a year to $26 a year. It is easy to collect dues when a home office can say to a doctor "You have saved three times this year on your malpractice insurance what your annual dues cost you."

There has come the time when home offices have to think. I can remember when about the only activities were the annual meeting and the exhibitors to be worried about, but today that has passed. All of us are worrying about the Veterans' Administration medical care program, about rural health. A leading newspaper in a state exposed the conditions in eleemosynary hospitals and overnight there sprang up from well meaning persons a statewide organization to cure all the mental health ills in this state without its ever having given any consideration to the medical problems involved. It went so far and so rapidly that a statewide mass meeting was held in the largest auditorium in the state. They suddenly discovered that they had no money, no office and no secretary, and yet there had been several thousand dollars sent in. This particular state association at a mass meeting offered the entire facilities of that office to this mental hygiene association. Who do you think is going to run that program? That was a home office assuming mature responsibilities.

The home office in Oklahoma has tried something new. We have gone into a newspaper advertising campaign. There has been placed a special assessment of $25 on every member of the state medical association. There will run in the forty-five daily papers of Oklahoma and in thirty-seven weekly papers monthly ads for one year. They are noncontroversial. In each ad there is one repeating statement, "How well do you know your doctor of medicine?" And then there is a short paragraph of explanation under it. We have not yet asked for any editorial comment, but an editorial entitled "Progress in Medicine" was written in the Medill, Okla., *Record,* a county newspaper. That, I think, is a home office in operation.

The question has been asked whether or not we have had any trouble collecting the $25 special assessment. Sixty per cent of the payment of that assessment was easy. The other 40 per cent has not been so easy. The time comes when you go to the county medical society and explain it. On the basis of our experience the voluntary and the personal appearances, I believe we shall collect almost 100 per cent.

A home office of the state medical association is going to have to become a place known and recognized for its honesty, integrity, and ability to answer whatever problem of medicine is reasonable, to any lay or professional or political subdivision. Until the home offices of state medical associations can do that they are not properly discharging their duties to medicine.

DISCUSSION

Mr. Charles S. Nelson, Executive Secretary, Ohio: Do you feel that there might be some possibility of standardization of the prices for booths charged by the state societies? Would there be some possibility of a standardization of the rules and regulations governing who may exhibit? Do you feel there is any advantage to the practice in some states of giving old exhibitors preference in assigning space?

Dr. L. Fernald Foster, Secretary, Michigan State Medical Society: Different conditions obtain in the several states. I can scarcely see how a standardization could be had in a small meeting. The standard relative to who is admitted to an exhibit I think could readily be done, possibly should be done.

Mr. Nelson: I understand that there are some societies that take the list of exhibitors for the last year or the last three or four years. They get the exhibitor folder first. Then at another interval, others get it. What do you think of that?

Dr. Foster: I think we base it on a sense of appreciation to our friends. In other words, there are those who support your state meetings consistently and there are those who support you sporadically and there are those who support you occasionally. We feel that those people who are with us constantly and those people who are interested in our presentations and are there year after year regardless of where we may go should be given preference. We have given up the idea of travel all over the state scattering things over a moderately sized city. We have two places, Detroit and Grand Rapids, where exhibit facilities are ideal. There is a variation in allocation of space in our two cities—one place we have space for 85 exhibitors, the other place we have an opportunity to accommodate 110. We seem to feel it is only fair to support those who are consistently supporting our show. That is probably the fair thing to do.

Dr. Thompson: We had a committee that was to look after the interest of the exhibitors and to bring all of the complaints of any exhibitors. The exhibitors knew that this small committee was representing them—not representing the medical association. They brought all the complaints in, and they were carefully studied and rectified where it was necessary. Then we just went a step further. We raised our prices. We have the full authority and the cooperation of every exhibitor that that price raise is legitimate and in order.

SESSION FOR EDITORS

DR. ROBERT N. NYE, Boston, Presiding

SATURDAY, DECEMBER 7, Evening

CHAIRMAN NYE: Having separate meetings for the editors and the secretaries is an innovation and I think it is a good idea. The editors should take great interest in what the secretaries have to say. That is part of our business. On the other hand, a lot of things that trouble us are not of particular interest to the secretaries.

The Medical Editor Consults His Readers

MR. THEODORE WIPRUD, Washington, D. C.: We made a survey of physician readers of the *Medical Annals of the District of Columbia* in 1939 and made a similar survey seven years later, less than one month ago. I also wrote a letter to editors of all state medical journals, inquiring if they had made a similar investigation. I was gratified with the response to the inquiry. I am not qualified to discuss the scientific aspects of a state medical journal. Dr. Wallace M. Yater, with the assistance of our editorial board, consisting of eight physicians in various specialties, passes on all scientific material. The editor also reviews all material of a general nature published in the Annals. Most of this is prepared by me or under my supervision.

In seventeen years' association with medical journals, I have observed that most editors are at times disturbed by the feeling that their circle of readers is small. The experienced editor endeavors to determine reader interest in the various departments of his medical journal. Most state journals are prepared for publication by a very small staff. Those responsible for the selection and editing of material have many other duties. Scientific editors are usually practicing physicians. Full time secretaries are so immersed in manifold activities they find it difficult to do justice to their journalistic assignments. It seems to me that, despite their handicaps, medical editors have discharged their editorial duties most creditably. I examine all state medical journals in search of new and distinctive material of a nonscientific nature and I have become acquainted with editors who do little work on their journals, and those who take their task seriously. Material published in a few journals is largely limited to papers presented before county medical societies and reprints from other journals. A majority of state medical journals are excellently edited. It is obvious that their editors are putting in an immense amount of time. The appearance of medical journals is uniformly good but appearances do not make up for lack of content. Our journals are not primarily advertising mediums, although some of them give that impression. Thousands of publications clamor for public attention. A few weeks ago I visited the Library of Congress, where I learned that there were 12,804 newspapers published in the United States today, and 6,693 periodicals. In the District of Columbia alone there are 14 newspapers and 202 periodicals. Not all these publications are of interest to doctors. However, there is a large enough percentage to furnish real competition for some 95 national medical journals in this country and Canada, and the state medical journals. No physician will read a state medical journal which does not present scientific material of genuine merit, editorial comments, articles of a general nature and news items interestingly written.

What efforts have editors of state medical journals made to determine reader interest? Of the 35 editors with whom I communicated, 30 replied. Of these, 28 had not conducted a survey or made any formal attempt to ascertain the views of readers. I quote from the reply to my letter from Dr. Robert M. Nye, managing editor of the *New England Journal of Medicine*: "About two years ago we sent a letter to 1,000 readers of the *Journal* requesting information regarding why they subscribed. The list was about equally divided among the geographic areas Connecticut, Ohio, Texas, Washington and Oregon. The report based on the returned questionnaire is as follows: Of the 551 replies received, 282 subscribers, or 51 per cent, stated that they subscribed to the *Journal* because of its total content. Six indicated that the original papers were their chief interest, 6 the progress reports, and 21 the case records. The remainder gave more than one choice. By assigning fractions to these three departments, the totals were as follows: original articles 160, progress reports 170 and case records 221. Thus, although the case records are the most popular, there seems to be no reason for making any radical change in the content of the *Journal*." Other comments might have been quoted. Some editors rated editorial material very highly where reader interest is concerned. Not so surprising was the popularity of personal items. Somewhat lower on the list in some parts of the country was scientific material.

The first survey of readers to determine reader interest in the *Medical Annals* was made in 1939. About 15 per cent of our membership at that time responded. Another attempt was made. Only about two weeks was allowed for the return of the questionnaire, which was hardly ample. The circulation of the *Medical Annals* at present is 1,900. However, the questionnaire was sent only to our 1,350 members. On Nov. 15, 1946, the date on which the returns were tabulated, 179 had replied. I am of the opinion that, in view of the type of questionnaire and the fact that many physicians who replied are prominent members of the profession, the response was satisfactory.

In response to the question "What material not now published would you like to see included?" 83 replied, 14 expressing themselves in complete satisfaction with the material presented, but 69 offering one or more suggestions. Nearly all wished more and better scientific material. Among their suggestions were the inclusion of abstracts of scientific papers presented before District medical societies, a list of recommended scientific reading, reviews of recent scientific literature, more case reports; reports on clinicopathologic conferences and articles on recent advances in medicine. A few urged that both sides of controversial subjects be presented.

The question "What material would you omit?" drew only 67 replies; 36 had no suggestions or felt that the journal should remain as it is. However, there was at least one vote against nearly every feature in our journal.

In answer to the question "Do you like the appearance of the *Annals*?" there were 169 replies, 155 replying in the affirmative, 3 answering no and 11 making criticisms. Nearly all the latter objected to the illustration on the front cover, some being vehement on the subject.

There were 127 who answered the questions "Do you think the layout of the text matter is attractive? How can it be improved?" Although 94 were thoroughly satisfied, 33 were critical or had suggestions to make. Again there was criticism of the cover. Also suggestions were made that the format be changed, the practice of continuing articles in the back of the journal be abandoned, that waste space be used, and that color be introduced in the text matter.

To the question "Do you patronize advertisers in the *Annals*?" 141 replied. There were 124 who said they patronized advertisers; a number gave complete lists of the names of those with whom they did business. Nine were not in practice. Eight said they did not patronize advertisers in the *Annals* as such. One physician said with regard to the advertisements "Never look at them."

The value of such a survey is that it gives the editor a better perspective. Defects in his publication which might go unrecognized are brought to light. Each questionnaire was signed by the returnee, otherwise it was disregarded.

Our method of surveying readers can be improved. I liked Dr. Nye's idea of writing a personal letter to his readers.

As far as the *Medical Annals of the District of Columbia* is concerned, I hope we can improve its contents from the standpoint of quality and that we can give it individuality which will make it be looked on by all our physicians as profitable and pleasurable reading.

It has occurred to me that so-called regional or national medical journal clinics for editors of state medical journals would prove profitable. At these clinics each department of these journals would be subjected to honest, objective scrutiny, discussion being led by topflight authorities in medical journalism. If editors can take the criticism which would undoubtedly be meted out, these clinics would contribute much to the improvement of state medical journals.

Chairman Nye: Mr. Wiprud brought in the *New England Journal of Medicine*. It is a little different, because it has a reasonably large outside circulation. Almost all the editors that Mr. Wiprud wrote to had not made a survey because they apparently thought that they knew more or less how the readers in the state felt about the journal. That is more or less the way we feel about members of the Massachusetts Medical Society. But with a fairly large number of journals going outside the state, we believed that it was only fair to try to find out why they subscribed. We sent out about 1,000 questionnaires and we got over 500 replies. The response showed that the subscribers were essentially satisfied with what they were receiving. One point Mr. Wiprud brought up was that he found that the majority wanted more scientific articles. When I took over the *New England Journal of Medicine* I decided that the chief function of a medical journal was educational, and that is the end toward which I worked. Our circulation has gone up. Possibly we don't pay enough attention to national and state medical affairs. It is very difficult for a state medical journal to handle the things we have had to handle in the last three or four years that have been on a national level. We have always kept our columns open to any of the various committees of the state society that wished to contribute.

Dr. Jonathan Forman, Columbus, Ohio: I assumed the editorship of the *Ohio State Journal of Medicine* in December 1935, when there was complete reorganization of the Journal and a revaluation of the whole program. The purpose of the Journal, however, has not changed since it was inaugurated in 1907. Prior to that, since 1847, the Ohio State Medical Society had published an annual volume of proceedings. If you go through the last two or three volumes you find a continuous discussion of the fact that there ought to be more frequent communications and that there ought to be a house organ connecting the component county societies with the work at the state level. It was as a result of that that the *Ohio State Medical Journal* was founded. When the society changed its name to an association in 1907, Dr. J. H. J. Upham, whom you all remember, assumed the editorship of that journal. It was done in his office for a long time. He had the generous help of a young woman who was hired as his stenographer, and she worked with the *Ohio State Medical Journal* up until a year ago. I am solely responsible for the *Ohio State Medical Journal* as far as its clinical work goes.

I want to emphasize what the preceding speaker mentioned, that we should have some topflight person, possibly not connected with one of our journals, dissect one of us. I would be glad to have him dissect the *Ohio State Medical Journal*. I also want to second what was said about having some clinics for the state medical journal. The *Ohio State Medical Journal* is fundamentally a house organ, 75 per cent of its space being devoted to reports of what local societies are doing, what the state society is doing, what its various committees are doing, what its council is doing, what its house of delegates does and to a report of the administrative offices of the various welfare agencies under the state government and those of the federal agencies located in the state capital. We have the usual number of obituaries and personals, and we try to emphasize, from time to time, things that are in The Journal of the American Medical Association. The *Ohio State Medical Journal* is a result of the cooperation of four men. We are about to take on another helper. My responsibility primarily is for the clinical side and for trying to make the clinical articles as educational as possible. I agree entirely that our function is not the reporting of original work and original ideas; it is bringing our readers up to date. We try to do that in the simplest and clearest possible style of writing. We believe, however, that each paper should reflect entirely the personality of the author. We are helped and we are handicapped by the fact that we are the repositories of papers read at the annual meeting. To make that worth while the committee on scientific work allows us to work with it closely, and the programs are planned not only with the meeting in mind but with regard to the appearance of the journal later. That presents problems which we have to work out and at which we have often failed.

I want to mention our Book Shelf. We do not attempt book reviewing. We make a very earnest attempt to cover all publications that have anything to do with interests of any physician: sex, economics, sociology, fiction in which there is a physician or dentist or a nurse as a character, or where the hospital or the medical school are the locale; textbooks and monographs that are of clinical interest. We try to cover the entire field with brief notices which follow a monotonous formula, in which we repeat what the author said was the purpose of producing the book. We comment on how we think he has succeeded in doing what he set out to do. Then we try to point out to whom among our readers this particular book would be of interest.

We have not been guilty of having white space. We have used the white space left over to fill in with quotations from your journals of the month before. We don't go back of the last month. When some paper breaks a half column, we amuse ourselves by a little column called "Keeping Up with Medicine," in which we comment on things we read and see. That makes up our journal which fundamentally is to interest the doctors of Ohio in their county and state societies. Then we try more or less on the side to do a job of education in the postgraduate or refresher sense. We produce in no sense a scientific journal.

We are circulating thousands of this little book in Ohio called "The Twenty-Five Points," in which we emphasize that there are twenty-four other things, including housing and welfare and nutrition and control of communicable diseases, that the public should attend to before they even consider the possibility of nationalization of the medical profession. It is turning out to be, as near as we can judge, an effective piece of educational material.

Chairman Nye: In the *New England Journal of Medicine* we aim to benefit the members of the state and district societies, but we try to do it on the basis of education, that is original scientific articles, medical progress, and the case records of the Massachusetts General Hospital.

DISCUSSION

Mr. Wiprud: Mr. Chairman, you stated that the primary function of your journal is education. I think a state journal has the obligation too to express opinions and try to create opinions and comment on them. One thing has not been emphasized in the analysis of our study which you have in your hand. A good many readers are not interested in medical history. Personally I find it most interesting.

Chairman Nye: I may have given the wrong impression. I do not believe that the entire function of the *New England Journal of Medicine* is education, but that is the primary function. On policies that face the medical profession in Massachusetts we cannot be accused of failing to carry articles that have to do with that sort of thing. We have been rather free in carrying articles on medical economics that are in favor of the attitude taken by organized medicine as well as by groups that oppose organized medicine. I think it is a good thing to have both points of view brought forward. Dr. Forman said they were embarrassed by the number of papers presented at the annual meeting. Do you publish all those papers?

Dr. Forman: No, but they are there for consideration.

Chairman Nye: We have the same problem. All those papers are submitted to the editorial board in the same way as any other paper that is sent in for publication.

Dr. Forman: I want to speak a moment on the historical side. One of our jobs is to be responsible for one issue of the *Ohio Historical Quarterly*. We have published in our journal what is called a Historian's Notebook, which I am quite sure is not very well read, but it makes a repository for historical material. With great effort we have been able to arouse interest in about ten physicians, two dentists and one public health worker over the ten year period. We publish one issue of the quarterly of the historical society each year. This small group has produced 228 papers, books and articles on Ohio medical history from the period 1787 to 1856. There have been five official histories of the commonwealth of Ohio published. Outside of a short essay by the late David Todd Killiam there has never been mention of medicine as having anything to do with the history of Ohio until this issue. We just recently published a six volume history, but every bit of it has been taken from these 220 articles which our little group has published. As the thing stops in 1856, there is nothing mentioned about medicine since. So we are going to correct that. We are telling the professional historian "It is obvious you don't have time. You have to have amateurs bring it to you, as far as medicine is concerned." I think there is a legitimate place in the medical journal for local history, even though no one reads it.

Dr. Walter E. Vest, West Virginia: As a matter of fact, don't a pretty good percentage read your historical article?

Dr. Forman: I never made a survey. I doubt it.

Chairman Nye: We carry historical articles every once in a while. Invariably five or six people tell me how much they enjoyed them. We have just asked Dr. Fitz to take the journal of a hundred years ago, go over the issues for the month and abstract interesting items. That means about a page or a page and a half. We have run it for three months and have had many favorable comments.

Dr. Everett M. George, Iowa: I should like to pay tribute to Dr. Bierring, who for twenty-five years has had charge of the history of medicine in Iowa in the section of the *Iowa State Journal.*

Dr. Morris Fishbein: One of the greatest difficulties that I see, with the advancement of some of the state medical journals, is that their editors have stopped studying. They have not advanced their journals; they have not, in general, at any time made anything resembling a major change. They haven't developed reader interest as they have seen it grow, in any one feature. They haven't made a real analysis of their problem as editors. Journalism today is not what it was when some of us began.

I have watched changes in the state medical journals over a period of thirty years. They are in a constant state of flux. Doctors like orderly material; doctors like to see material fairly well departmentalized, so they don't have to look too far for what they want to find. The idea that you are going to create reader interest by suddenly surprising the doctor with a poem at the end of an article is not helpful. He doesn't want a poem at the end of an article on cirrhosis. He may like a little historical reference to cirrhosis of the liver at that point, to somebody's first communication on that subject. If you are looking for a filler to put in at that point, there is a journalistic technic that involves finding a filler that is somewhat apropos to the subject that has just been discussed. The chief interest in journalism is to make it live, and a journal will reflect in every instance the character of its editor. Some of them are dynamic; some of them are lethargic; some of them are very staid, and some of them are disorderly. That is reflected in the publication.

I am impressed with the proposal to hold a clinic on journals. That is the ideal method of instruction. I am impressed with the idea that we should not have sameness in the state medical journals. They ought to differ. There need not be a pattern for a state medical journal. Success would seem to me to lie in departing a little, at least, from other patterns. It is a feature of the *New England Journal of Medicine* that it publish the clinics which it does. It is a feature of the *New York State Journal of Medicine* that it has taken over the symposiums that are developed at Cornell University dealing with the field of therapeutics. There are other features in other publications which are characteristic of those publications, and that is what gives them individuality and makes them worth while.

A journal will reflect, in every instance, the amount of attention and care given to it. It is easy, having received a communication from a doctor, to write at the top "To the Editor," at the bottom, his name and send it to the printer. It is another thing to study a letter, to determine how much of it is useless, to send it back to the doctor to get his approval of it, to edit the communication and to make sure you have concentrated reading matter instead of a lot of continuous discussion that isn't very relevant. The same thing applies to editorial material. There are fundamental rules of journalism that have to do with the creation of a lead in order to catch reader interest at the first sentence.

Many of the scientific contributions take far too long to get into the subject and would be greatly improved if, when the manuscript is received, the first page is eliminated entirely in many instances, at least the first two paragraphs. That means attention, and many editors do not give that attention to their contributions.

Journalism is something to which a man may be partially born but which is made by study and education in the field of journalism. We have a rule each day to go through the exchanges, and the moment a subject is found which seems to be developing interest in the medical profession, because either of its newness or of its controversial character or of some special quality, that is selected at once for comment. The most successful magazines in the United States, in either professional circles or the circles of general magazines, make up a large portion of their content from material that the editor develops rather than from material that comes into the office in routine.

Dr. George W. Kosmak, New York: These two papers as well as the remarks of Dr. Fishbein give much food for thought. Most of us coming here as editors want some help in our problems. One of my friends complained that there was too much advertising material in our state journal. I had the business manager go over the advertisements carried during the last year. We found that in only one issue did the advertising pages exceed the text pages, that our average advertising content amounted to about 40 or 42 per cent, and the rest was text material. How can you get members of the state society to whom their state journal is sent as the official organ to go through it? That is difficult in our case. A questionnaire such as you propose would be a costly procedure. We have a circulation of about 23,000 copies. We have over 20,000 members of the state society enrolled, each of whom gets the journal. Even to reach the members would be a costly proposition. We thought over all sorts of schemes to get people to open the journal when it comes to them. I should like to find the solution to those problems. The state journal, in our opinion should fulfil three purposes: It should primarily be an organ of expression for the policies of the state society. Secondly, it should have a satisfactory scientific content. Thirdly it should be a medium for the dissemination of news in the state. We have had difficulty in New York State in getting local news. No matter whether you delegate the secretary, even agree to pay him, you simply cannot get it. The only way we can get county news, outside of the few bulletins issued by county societies, is to have a clipping bureau supply us. That is what we do. There is a competitive element that the state journals have to meet in New York, and that is the local county bulletins. The Medical Society of the County of New York not merely publishes a news bulletin but includes scientific papers that are read at the meeting. We decline at least 20 per cent, sometimes 25 per cent of all the contributions sent in, and yet we haven't room enough to publish the good ones. I should like to get an opinion or advice on how the paper situation can be remedied. With our circulation of 23,000 copies we have more difficulty in getting paper than the journals with a circulation of a few thousand. As a result, the journal is not able to improve its appearance or to extend its text pages. I should very much like to publish a page or two headed "You may not have seen this," in which I could put extracts from your journal or from Washington *Annals* or from the *Ohio State Medical Journal.* We simply cannot publish abstracts. We haven't the space.

Chairman Nye: I am sure that all of us have run into this paper shortage. We manage to get our paper by paying twice as much, and the paper we get isn't much better than newsprint.

Dr. Blackerby: I should like to ask Mr. Wiprud to comment on the value of one issue of a journal being devoted to a particular field of medicine, when there are so many fields.

Mr. Wiprud: You will note that some of our readers suggested we devote one month's issue of our journal to a field. I thought it a good suggestion. I realize that our survey was fragmentary, but I think it has possibilities. I think, too, that large circulation journals will have to find a way of sampling their readers rather than trying to canvass all of them.

Dr. Vest: We have tried that. Our January issue will be devoted to tuberculosis. We have tried it two or three times and have always got comments.

Dr. Wingate M. Johnson, North Carolina: We had one issue on geriatrics.

Chairman Nye: It seems to me that you would lose a lot of interest; it would be interesting to only one group.

Mr. Wiprud: You couldn't do it continuously.

Sunday, December 8, Morning

Dr. Julian P. Price, Florence, S. C., Presiding

Chairman Price: At this time I present Dr. Robert S. Berghoff, president of the Illinois State Medical Society.

Dr. Robert S. Berghoff introduced the next speaker: Governor Green.

The Field of Public Health

Hon. Dwight H. Green, Governor of the State of Illinois: Officers of the American Medical Association, Editors and Secretaries from all over the United States: There is a field in which you as the spokesmen and leaders of the medical profession and we in government have a common concern—a common responsibility to the people of our communities, our state and our nation. That is the field of public health.

The complexities of modern life have forced a tremendous expansion of governmental services to the people, and nowhere has this expansion been greater than in the field of public health services. It is significant that this expansion has almost invariably followed the recommendations of the leaders in the medical profession. I am impressed by the fact that the biggest and busiest men in your profession—in sharp contrast to the leaders in many other professions and businesses—are most willing to give their time and energy to public problems connected with their work.

America is deeply indebted to individual physicians and medical organizations who have taught us the importance of health conservation. And it is not surprising that while the best of that thinking has produced such a sound national health program as the ten point plan of the American Medical Association, some loose thinking has produced other proposals which you and I both view with alarm.

It is natural that, when various collectivist philosophies were sweeping the world, proposals for some form of state medicine or socialized medicine should take hold with many people. Those proposals have been alluring to many laymen because they have been offered in connection with sound health measures which have your support. It has been difficult for you to oppose a program which threatened to stifle the free enterprise of the American medical profession under a federal bureaucracy far beyond anything America has seen even in the war and postwar years, because that program was offered under the attractive name of "sickness insurance." I believe that fortunately your profession and the people have been saved from any immediate danger of a medical bureaucracy. The national election last month was essentially a referendum on the issue of federal bureaucratic controls versus private enterprise. The verdict was so strongly for private enterprise that I am sure you will find little disposition in the next Congress to proceed further with socialistic experiments.

The medical profession was lucky that the theorists and the bureaucrats, before they got around to experimenting on you, engaged in some vivisection on American industry and agriculture. It was an elaborate series of operations, with many complicated names.

The renewed confidence which America has expressed in private enterprise will not be sustained if we revert to the mistakes and the indifference of the past. The medical profession, if I am correct that it no longer need be on the defensive, has a golden opportunity for greater public service. It should push with all vigor its ten point national health program. In addition it should foster a healthy competition in which its members would seek not only to provide for their patients the finest possible scientific service but to provide it with all the efficiency and economy of the most modern business methods. The medical profession has always been relatively free from governmental interference. The regulations imposed on it have been mainly those proposed in the public interest by the profession itself. That is as it should be.

Yet the realization that health is the first blessing of life, without which all others are meaningless, and that disease is an ever present peril, should move all men of good will, in science and in government, to the fullest cooperation for greater service to mankind. We should welcome to that partnership the splendid men and women of religious and philanthropic organizations dedicated to the aid of the sick and the handicapped. In short, we should preserve the American way of life even in the endless struggle with death.

Chairman Price: If any of you have questions you would like brought up for discussion or that you yourself would like to discuss, please write them out. We will have an hour and a half of open discussion, free for all. First I should like to ask Dr. Douglas Cannon to give the report of his section.

Reports from Sessions for Secretaries and Editors

Dr. Douglas L. Cannon, Montgomery, Ala., presented a summary of the papers read before the meeting of the State Secretaries.

Dr. Robert N. Nye, Boston, Mass., presented a summary of the papers read before the previous evening session of the Editors.

Open Forum

Chairman Price: I will ask Dr. Shanks and Mr. Sethman to bring forward any questions. Has anybody any problem he wants to ask Mr. McDavitt?

Question: "In view of your remarks, do you think it safer for a state association to seek exemption under 101 (7) instead of 101 (6), if the association plans a good deal of aggressive legislative activity?"

Mr. McDavitt: I think that is the only solution. There is no possible disadvantage, as I see it, to being classified under 101 (7) as a business league if we discard any false sense of pride that we have in being called a scientific or educational association. The fact that a medical society is not given exemption under 101 (6) doesn't necessarily mean that the government does not regard it as a scientific or educational organization. It simply means that it doesn't conform to all three of the tests that I spoke of yesterday, namely, while it is scientific and educational, possibly a substantial portion of its activity does consist in carrying on legislative activity. If so, it is not entitled to exemption. The only disadvantage I see, and I don't actually believe myself that it is a disadvantage, is the liability for social security taxes. That should not be much of a financial burden to the average medical society, and it does give a certain advantage to the employees of the association. It gives them the benefit of old age benefits. It does afford them the security that may be had from unemployment compensation, that is, in the event they are thrown out of employment or not employed they are entitled to about $20 a week for twenty weeks.

Question: "If a state society in filing its income report simply classifies itself as a business league, and that has been accepted by the Revenue Department, should the effort be made to obtain any ruling on it, or would that quiet acquiescence be sufficient?"

Mr. McDavitt: I don't think it is safe for a state society to classify itself. I think, particularly with respect to the income tax, it would ask for a ruling from the Commissioner. I don't know of any state society that has been required to pay income taxes. The chances are you will be exempt from income tax. What the government is primarily concerned with is the question of social security taxes. I think, to be on the safe side, I would ask for a ruling as to your status under the income tax act. Seven states, to my knowledge, are not paying income taxes and never asked for a ruling as to their status. I don't have any fears that the government is going to come back and hold them liable for income tax, but the government, when it does catch up with the situation, is going to assess them the proper social security taxes, and they are going to be liable not only for the taxes for the back years but for interest and penalties.

Question: "How can state and county societies better promote good public relations? What type of public relations should be attempted first?"

Mr. Swart: There is no simple answer to that question. The first thing to do is to have made a very comprehensive study of where you are at the present time, what people think of your organization, what the membership thinks of it, what the community in which it operates and exists thinks of it. When you have found that out, you can consult among the medical profession and with people who are acquainted with public relations and with public relations elements in the national office to determine what course of action to take on the basis of the facts known. There have been cases in which organizations, assuming that people did not approve of certain aspects of their program, have talked themselves blue in the face trying to sell the community on things on which the community was already sold and, at the same time, assuming that the community gave complete endorsement to some other policy or activity, missed an opportunity to tell the people about that and to create favorable public opinion, and all the while unfavorable public opinion was quietly gnawing away at the foundation of their status in the community. The simple answer to the second half of that question is that the place to begin is to find out where you are now and operate from there with the best thought and the best advisers that you can get in touch with.

Dr. Alfred Stahl, Newark, N. J.: I should like to have the last speaker discuss something mentioned by the gentleman from Oklahoma in regard to advertising in the daily press. I think that is a pertinent question.

Mr. Swart: I don't know the issue. Are you referring to some particular issue or some particular advertising?

Dr. Stahl: It was brought out in Mr. Graham's paper.

Mr. John Hunton, California: The question of newspaper advertising has been met in California. At present the California Medical Association is expending about $100,000 a year in newspaper advertising. It is being done on an organization basis, and it is being done in a series of community campaigns to enroll as many people as possible in all the voluntary prepayment plans in the state. I say "all the voluntary prepayment plans" because our method has been this: We have set up what we call a coordinating committee for voluntary health insurance. We have included in the membership of that committee not only California Physicians' Service but the three Blue Cross plans operating in the state, and 110 commercial insurance companies which are writing some form of indemnification insurance for health and accident. That committee is staging, county by county, a statewide drive to enroll as many people as possible in the voluntary prepayment plans and in the county campaigns. An important part of the publicity has been newspaper advertising. We have found that when we run a piece of copy 20 inches by 4 columns we can generally count on about twice that much copy being run by local merchants who pick the copy up later, put it over their own signature and compliment the California Committee for Voluntary Health Insurance on putting on a drive in that county. The most popular source of support in that has been from the druggists. The druggists of one community after another have followed up on that advertising, sometimes taking our own mats, cutting out our name, and putting in their own. It has been very beneficial, not only from the point of view of drawing in direct responses from the advertising but it has done something which we have never before been able to accomplish in the state. We have 700 newspapers, a great many of them small weeklies. Never before have we been able to get real support from the newspapers because the answer constantly comes back "Why should we give the doctors any support when they don't advertise and chiropractors do?" We now have an answer to that. When we started our campaign we went to the California Newspaper Publishers' Association and said "Gentlemen, we are going to spend a lot of money with the newspapers. We are going to advertise in every one of the 700 newspapers in California. Each of the 700 papers in the state is receiving a minimum of 100 column inches of advertising in a period of twelve months. We have found the response from the editors, in publicity, has been far beyond anything that we expected when we started the campaign.

Dr. Weld: You pay for it all out of your own society?

Mr. Hunton: The financial support from the insurance companies has not been great. The California Medical Association is paying most of the freight.

Dr. Lewis J. Moorman, Oklahoma City: In Oklahoma many of us have long felt that doctors, in pursuit of science, have neglected the art of medicine; in other words, neglected the patient. Therefore we have lost the rating that the so-called good old family doctor used to have. Apropos of this, somebody recently asked me what had become of the good old family doctor. I replied "If you will find me a good, old fashioned family, I will produce a good, old fashioned family doctor." In keeping with the feeling that we are losing our hold on the public because we have become ultrascientific and have neglected to win the love and respect of the patient, we decided, through the avenue of advertising, to let the people know what modern medicine is doing for the modern public. Consequently we assessed our membership for the purpose of carrying on an advertising campaign, with a view of transmitting to the people, even in rural communities, information with reference to what modern medicine means to the people. We believe that is the best way to combat such proposed measures as the Wagner-Murray-Dingell bill. Already these advertisements have appeared in our leading daily papers and in our weekly country town papers, and we have had very favorable editorial comment.

SECRETARIES AND EDITORS

Dr. Ray T. Woolsey, Salt Lake City: We have newspapers in Salt Lake City and, very peculiarly, we get newspaper space covering modern day advances of medicine, about two and one-half to three columns in the morning paper of Salt Lake City that has a statewide circulation, without cost to the medical profession. We prevailed on the editor-manager of the morning paper there to assign a reporter who had been covering state conventions and who is rather conversant with medical subjects, who has the ability of converting medical terminology to language that the lay public can understand, and writing these articles after interviewing doctors in various phases of medicine. We find a great tendency for some of the people in our country to board an airplane now, a train, travel east and get back to the large clinics, only to find out, after they have gone through the mill, that they were sent back home because the doctors at home could do pretty nearly as much for them as they could do in the large clinics.

This thing was started primarily to try to let the people of Utah and the intermountain territory know that there were doctors in that territory who could do just as much for them as could be done in the larger clinics in the Middle West. I think it is paying dividends, because we find that people are staying at home now and have faith in their local doctors. We are carrying it even so far as to encourage the people to stay in the small town. We feel that, if we are going to get doctors to stay in the small towns, in the valleys in between the mountain ranges in Utah and Idaho, we are going to have to keep the people there and let them go to their doctor in that area. On that basis, these articles are written by this editor and by this reporter. We haven't been able, of course, to do anything in regard to fighting the costs, as Mr. Hunton from California said, because we don't buy advertising space, but I think we will start doing that, just so we get editorial support. We did get support from the newspaper against the Murray-Wagner-Dingell bill. Whether they were rallying behind medicine or their own private interests, I don't know. But we are getting our space in Salt Lake City through the graciousness and the public spirited attitude of the owners and managers of our local papers.

Mr. James G. Burch, Connecticut: I have been public relations counsel for the Connecticut State Medical Society since the fifteenth of August. We have done nothing as yet in advertising in Connecticut newspapers. Our main program has been to study thoroughly, first, the attitude of all our editors. I have visited every editor in the state except, perhaps, a dozen editors of weekly newspapers. We have twenty-one daily evening papers, six morning papers and a half dozen Sunday papers. On this matter about which I have been asked to talk with you the cultivation of our wire services, we find that the wire services in Connecticut cooperate very closely, practically without request, on a pure basis of the value of the news. If our story is important enough —and we feel this way about it now, we would prefer to try to get over the Associated Press and United Press hurdles. We feel that if the wire service will accept our story the newspaper editor, when it comes through on the teletype, cannot fail to accept it. We also use the names of physicians who are connected with the story in any way. That is an encouragement to the local paper to use the story. However, we have had occasions when general stories were used very widely throughout the state, for instance, on the subject of medical care for veterans. In developing the stories on that subject, we carefully went into it and spent quite a bit of time determining how we were going to tell the story before we got our final draft.

Oftentimes a newsman will come in and write the story, but you mustn't forget that he is writing for the newspaper. If you have some very important section of the story which you wish to use as a lead and to emphasize, then you must study the story thoroughly, and the entire situation, to see that when you suggest that to the newspaperman it is a legitimate lead, that he doesn't get the idea that you are trying to slant the story, that you are trying to be unfair, that you are trying to tell him what he is going to write in his paper, or that, in any way, you are trying to censor the news. Most newsmen are sensitive about that. If you think these things out when you send a story through, and the story is written, you will find that, when it is developed properly, the newspaper will not only run it but give good space to it. In our state we have between 225,000 and 250,000 veterans of all wars. In writing the story of their medical care we developed the phrase "home town medical care for veterans." All through these stories, once that key is set, each time we use a story on the medical care of veterans we repeat "home town medical care plan." It is a local program. It moves, in line with our general program, to bring the problems back home to the people, where they then can become acquainted with them and understand them more thoroughly than some of the problems in the national field. Then the road to improvement seems much clearer to them.

COOPERATIVE MEDICAL ADVERTISING BUREAU

Chairman Price: We will pass on to another group of questions about the Cooperative Medical Advertising Bureau.

Mr. Jackson: The standardization of colors has been a difficult task for all the journals to solve. I have prepared a chart showing a variation of eight colors, two shades of red, medium brown, orange, sky blue, deep blue, green and yellow. With the use of screen and ben days we get a variation for each color. We are going to have these prepared in small pamphlets. After the first of the year we hope to send half a dozen copies to each of the journals and to the advertisers and agencies using color. So, during 1947 we are going to ease up that difficulty. They will just have to specify our deep red or bright red or orange or yellow, and the printers of The Journal office will know what the advertiser wants. "What are the advertising prospects for 1947?" The prospects are good. The contracts in and on record amount to $535,000. The anticipated renewals, when they expire during the year, amount to about $105,000. That brings the total of about $630,000.

Question: "How many journals have had an increase in printing costs this year? How many journals have had a 10 per cent or less increase?" It looks like nine. "How many have had between 10 and 20?" Thirteen. "How many have had more than a 20 per cent increase in printing costs this year?" Two.

STATE AND COUNTY SOCIETIES

Question: "What technic is most successful in interesting the individual physician in the problems of organized medicine and in securing his active participation in the work of his county and state medical societies?"

Dr. Anderson: I don't feel any particular qualifications for answering that question except from a limited experience that I have had in field work. I know that many of our state societies have done a good job in field work. I think that is the answer. I don't believe that you can get the ordinary practicing physician keenly interested in problems of the state association or even of his county medical society unless you get him across the table from you and get him to state his complaints and then have a free-for-all discussion. In Texas we are getting ready for one of the hardest legislative battles we have had in a long time. We are wanting to change our licensure setup. We have a board of medical examiners on which osteopaths are represented, also homeopaths, eclectics and regulars. We are going into our state legislature in January in an effort to change that setup and have separate boards, with a basic science board that will screen them. To sell that legislation, we first had to be sure that we could activate our own members, that they would be familiar with it. So, my experience in connection with field work has been largely that. I visited forty-six county medical societies, talking to them in groups, small as well as large societies. I asked any one who had any complaint about how his state society was being run or if he had any criticism of the American Medical Association, to speak up. That experience has taught me that what is more needed to activate individual physicians in their interest in county, state and national organization is good field work.

Mr. Meadors: The most direct and immediate source of stimulating activity by the individual physician is to give him something specific to do. There will be some occasion in connection with some county or state program in which you can call on some specifically designated physicians in the various counties to supply you with certain information, to contact members of their society. It has been our experience, almost without exception, that our request for such information from any part of the state has met with immediate cooperation and with stimulated interest on the part of those whom we contacted. Second—and this fits in with what Dr. Anderson just said—secure the opportunity to talk across the table, or frankly in a meeting of the group, and explain to them what you are trying to do and their part in it.

Dr. P. E. Blackerby, Louisville, Ky.: Would you briefly describe the operation of your statewide committee on behalf of your medical school, just how it functions?

Mr. Meadors: The committee originally consisted of seventeen, including a member from each of the districts, the officers, including the director of public relations and counsel. Shortly after it was appointed a meeting was called by the president in the capital city of our state, at which the cause of the medical college was presented fully. A short time later the committee met in Charleston, went over the plan and facilities of the medical college, a personally conducted tour, you might say, by the dean and members of the faculty, had lunch with the trustees of the medical college and learned what they needed in the way of physical improvement. In the meantime some agitation had arisen outside the profession for removal of the college from Charleston, where it had been throughout its history, to Columbia. In order to be perfectly fair a meeting of the committee was arranged for Columbia a few weeks later, at which the legislative delegation of Richland County, in which Columbia is situated, was given a full hearing. All the committee meetings were executive. Following each meeting a release was given to the press. The public hearing to which I have just referred was not, of course, executive, but immediately following it the committee went into executive session and determined that it would not recommend removal of the college but its expansion in Charleston. That announcement was given clearly to the press. That completed the preliminary activities. Then when it was enlarged to a committee of forty-six, including a member from each county medical society, each of those members was requested to contact personally the members of the legislature in his county, individually, as a member of the committee himself, or that he have some other physician in the community do so or some personal friend who was not a physician and had a direct contact with the member of the legislature. All of that was going on previous to the meeting of the general assembly. The stage was all set by the time the general assembly convened. Then we kept in touch with the situation, did what conservative lobbying might be done in the meantime.

On the weekends, this committee continued to be active in the home communities of the members of the general assembly. I think that about sums it up.

THE BASIC SCIENCE AND COMPOSITE BOARD

Dr. Stewart G. Thompson, Florida: In Florida the Basic Science Board and the Board of Medical Examiners are operating nicely. A composite State Board of Medical Examiners was established. On that board were representatives from regular doctors, homeopaths and eclectics. A number of years later the statute was amended to eliminate the stated proposal of appointees to the composite board from the three branches, so that now the ten members to the State Board of Medical Examiners can be appointed from medical doctors who hold licenses to practice in the state. This procedure has worked out very satisfactorily for a number of years.

A state examining board in the basic sciences was brought up at many meetings of the state legislature over a period of ten years. All bills proposing to include representatives from chiropractors and naturopaths were defeated. Finally, a bill was proposed for a Board in Basic Sciences with members appointed by the Governor from the professors of the institutions of higher learning. This Basic Science Board has been in operation for a number of years and has been satisfactory. The State Board of Medical Examiners require all applicants to have first passed State Board of Basic Sciences before being eligible to take the examination of the State Board of Medical Examiners. The reasons are obvious. Before this Basic Science Board was in existence, it was possible for naturopaths and chiropractors to receive a license in the state without first having had the proper education and training.

Dr. Walter E. Vest, West Virginia: I hear from some of those who have taken your basic science board examination that the trouble with it, from the standpoint of the medical candidate, is that the basic science board does not know enough differential diagnosis, between pure science and science as applied to medicine.

Dr. Thompson: The basic science examination has been a wonderful thing in our state. The uneducated men just cannot pass it. I don't know of a single naturopath or chiropractor who ever passed the basic science examination.

Dr. Holman Taylor: Did I understand you to say that you have separate boards for the separate branches of the healing arts, the so-called schools?

Dr. Thompson: Yes, sir.

Dr. Taylor: Do those enabling acts setting up those boards require that the applicants for license, at the hands of the board, keep to their little special sort of practice, cultism? In our state we tried this basic science business at the last session of the legislature. The osteopaths set up a bill that gave them every advantage and every responsibility that was given to the unlimited license or M.D. group. What steps do you take to see to it that that sort of thing doesn't happen? How do you require that these separate boards confine their examinations to that peculiarity and confine their responsibility? When it becomes a law, the osteopaths claim to do everything the doctor of medicine does when he introduces his bill. How do you prevent them from enacting that into law? The legislators tell us to "wait a minute." They ask "What business is it of yours?" We tell them but they say "Well, we gave you yours; we will give them theirs." So the osteopaths show up with the same sort of responsibilities, the same sort of opportunities, prerogatives and privileges that the educated doctor has. How do you go about stopping that?

Dr. Thompson: If they introduce a bill we don't like we get a copy of it that day. We don't wait until they get past second or third reading. If there is something in there that the doctors don't want, they have their senator or representative get up and amend it and take out the things we don't like. You have to stay there and fight to the finish. The background of it is this, which is the most important thing of all. Before the legislature meets, we try to find out who the family physician is of each senator and each representative. He will listen to his family physician. If you can educate your family physician on what is necessary in medicine, then he can talk to his senator and his representative, and, when it comes to the floor, more than half of your troubles are past.

PUBLISHING NAMES AND ADDRESSES OF OFFICERS

Question: "Would it be possible to publish both the medical and the executive secretaries' names and addresses, in view of the fact that many states now have two secretarial officers?

"Would it be possible for the A. M. A. to publish annually to the state secretarial officers the names and addresses of all county society secretaries?"

Dr. Lull: I think it would be possible to publish the names and addresses of both secretaries in the program. As far as The Journal is concerned, I would have to consult Dr. Fishbein, and I have grave doubts if that could be published in The Journal, because of lack of space. We can supply to the state secretaries a list of all county society secretaries once a year. They change often. I might remind the state secretaries that our lists aren't up to date because sometimes the secretaries of the state societies don't keep us informed of the changes in these officers.

COSTS OF RADIO DRAMATIZATIONS

Question: "Would you please discuss the costs of the A. M. A. radio dramatizations?" We are interested in what it might cost a state society in round figures to employ professional talent to create radio dramatizations.

Dr. W. W. Bauer: The answer to that question depends, to some extent, on where you are and whether or not you are working in stations where union rates govern. First you have to have a script. Script writers get prices depending on their reputation. The very least that you could expect to buy a script for a fifteen minute dramatization is from $50 to $75; for a thirty minute dramatization from $100 up. The cost of actors under the American Federation of Radio Artists' scale is in two general classifications: first, the sustaining or nonrevenue program, in which your dramatizations would fall; second, the commercial. Ordinarily the commercial would not concern you, but there is under negotiation at present a demand of the American Federation of Radio Artists that there shall be an elimination of the distinction between sustaining and commercial programs. If that bargaining demand is granted by the networks and the recording companies, then you will have to pay the commercial rates. The sustaining rate is, for a fifteen minute program, $15 plus 10 per cent, plus 10 per cent, plus 20 per cent. It was $15 plus 10, plus 10 until the recent negotiations. Now it is plus 20 on the total. That is the sustaining minimum. For a thirty minute program it starts at $25 plus 10, plus 10, plus 20. If you go into commercial, then you would have to pay, in addition, for the rehearsal time. I am not clear as to all the details, but rehearsal time starts at a basic $6.60 per hour, and it takes three hours to rehearse a fifteen minute program and five hours to rehearse a thirty minute program. That is in general, what you might expect to pay.

In round numbers, we figure that our fifteen minute dramatizations which we have been distributing to you on platters will cost us, for a series of thirteen programs, roughly, $5,000 for the masters. From there we make our pressings, and it is the pressings that you get. So that, if you go into dramatization at all, you must anticipate costs that will far exceed any other technic. Even the interview technic is not without its costs, because we must have a script. To diversify the program we must either bring doctors to us at our expense to record in Chicago or we must send our interviewer to where the doctor is. We have distributed to you on platters some musical programs. There, again, you run into costs of script; you must have an American Federation of Radio Artists announcer and you must have a union musician if your platters are going to be recorded and are going to be distributed to stations where the staff is unionized. I should say that you could hardly do much in a state medical society program of dramatizations, whether you record them or whether you put them on the air alive, with less than $10,000 for thirteen weeks. If you are doing a thirty minute program for thirteen weeks, and it will not pay you to do it for any less than thirteen weeks, you will have to figure on from $400 to $500 a week for your costs. I am talking only about production costs. There is no estimate for time on the air, because you are not expected to pay for time on the air. Your time should be given by the radio station in its contribution to a joint public service.

Official Notes

THE ATLANTIC CITY SESSION

Entry Blanks for the Thirty-First Annual Golf Tournament

The American Medical Golf Association will hold its thirty-first annual tournament at the Atlantic City Golf Club, Atlantic City, N. J., June 9, on the occasion of the centennial of the American Medical Association. The tournament will be an eighteen hole competition, and about one hundred prizes will be awarded at the dinner at the club. The chairman of the golf committee is Dr. Gene A. Gruhler, Atlantic City. Any member of the American Medical Association interested in playing at the tournament may secure entry blanks by writing the secretary-treasurer of the golfing association, Bill Burns, 2020 Olds Tower, Lansing 8, Mich

Washington Letter

(From a Special Correspondent)

Feb 27, 1947.

Senator Murray to Reintroduce Wagner-Murray-Dingell Compulsory Health Insurance Bill

The Wagner-Murray-Dingell bill for compulsory health insurance, which failed to reach a vote last year, will again be presented to Congress by Senator Murray, Democrat of Montana, one of its original sponsors. A battle is indicated between proponents of compulsory insurance and sponsors of a voluntary plan, introduced by Republican Senators Taft of Ohio, Smith of New Jersey, Ball of Minnesota and Donnell of Missouri The Democratic measure, first supported by President Roosevelt and later by President Truman, would provide health insurance for all wage earners except federal and state and railroad employees and their dependents. Participants would receive medical care paid for by taxation in some form. Senator Wagner told Congress that 3 billion dollars would set up the plan and that it would cost from 1½ to 3 million to administer.

Remedies for Incurable Diseases Sought Through Atomic Energy

Dr. Elizabeth Smith Friedman, research analyst, told a luncheon meeting that atomic energy research seeks to provide remedies for heretofore incurable diseases. She said that private research is being pressed at two national laboratories in the East and Middle West, with a third planned for the Far West. Universities in these areas are sponsoring atomic research in medicine, chemistry, metallurgy, ceramics and all phases of nuclear physics. The speaker asked for public pressure on Congress and the United Nations to agree on a working United Nations atomic energy commission Official Washington turned out *en masse* for the preview of the atomic bomb film "The Beginning of the End."

Tests of New Chemical Compounds at National Cancer Institute

Members of the National Advisory Cancer Council revealed that the National Cancer Institute has developed new chemical compounds for treating cancer and they are being applied to human and animal sufferers from the disease Some success in destroying malignant growths in animals has been reported. Dr. Robert S Stone, professor of radiology, University of California Medical School, said that development of atomic energy had provided cancer specialists with new materials for cancer research. Radioactive phosphorus and iodine and substances derived from the Oak Ridge atomic pile are being tested in research

Employment of Practical Nurses in Hospitals

A change in the policy of nurse examining boards, which have discouraged employment of practical nurses in hospitals, may result from the current serious shortage of nurses In the District of Columbia proposals to relieve the current nurse and auxiliary nurse shortage by training practical nurses are being studied by hospital superintendents Only Doctors Hospital now offers practical nurse training, which was encouraged in a recommendation of the American College of Surgeons. Recently about 20 practical nurses were employed at Providence Hospital to meet the shortage. Some critics attribute the lack of graduate nurses to stiff requirements for training, time involved and low pay as compared with salaries paid business women.

Doctors Asked to Join with Lawyers in Combating Court Problems

Doctors were urged to try preventive medicine in the field of crime by District Court Chief Justice Bolitha J. Laws in an address before the annual alumni reunion of George Washington University Medical Society. He urged doctors and lawyers to work together in solving problems of alcoholism, divorce and criminal psychoses. He believes that medical examinations might reveal which are potential criminals

Status of St. Elizabeths Hospital

Senator Taft explained through a spokesman that he did not intend to transfer supervision of St. Elizabeths Hospital to the Public Health Service, as provided in the original draft of the national health bill. The senator was of the impression that the hospital was under the Public Health Service. It is his intention to leave its status unchanged while transferring the parent agency to the proposed federal health authority.

Closed Hearings on Lemke Antivivisection Bill

The House of Representatives District subcommittee on health, education and recreation held closed hearings on the Lemke antivivisection bill, with subsequent hearings to be open.

Coming Medical Meetings

Alabama, Medical Association of the State of, Birmingham, April 15-17. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for the Study of Goiter, Atlanta, Ga., April 3-5. Dr. Thomas C. Davison, 478 Peachtree St., N. E., Atlanta 3, Secretary.

American Association of Anatomists, Montreal, Canada, April 3-5. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Laryngological, Rhinological and Otological Society, St. Louis, April 25-26. Dr. C. Stewart Nash, 288 Alexander St., Rochester 7, N. Y., Secretary.

American Otological Society, St. Louis, April 21-22. Dr. Gordon D. Hoople, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

Arkansas Medical Society, Little Rock, April 17-19. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 17-20. Dr. Glenn D. Carlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Florida Medical Association, Miami, April 20-23. Dr. Robert B. McIver, P. O. Box 1018, Jacksonville, Secretary.

Georgia, Medical Association of, Augusta, Bon Air Hotel, April 22-25. Dr. Edgar D. Shanks, 478 Peachtree St. N. E., Atlanta, Secretary.

Iowa State Medical Society, Des Moines, April 16-18. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Maryland, Medical and Chirurgical Faculty of, Baltimore, April 22-23. Dr. W. Houston Toulson, 1211 Cathedral St., Baltimore 29, Secretary.

Michigan Postgraduate Clinical Conference, Detroit, Book Cadillac Hotel, March 12-14. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mid Atlantic Section, American Urological Association, Washington, D. C., Hotel Statler, March 20-22. Dr. Theodore R. Fetter, 255 S. 17th St., Philadelphia, Secretary.

Missouri State Medical Association, Kansas City, March 30-April 2. Mr. Thomas R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Executive Secretary.

New Jersey, Medical Society of, Atlantic City, Haddon Hall, April 22-24. Dr. Alfred Stahl, 160 Lincoln Ave., Newark 4, Secretary.

Northern Tri State Medical Association, Detroit, April 8. Dr. John L. Stifel, 232 Michigan St., Toledo 2, Ohio, Secretary.

Oklahoma State Medical Association, Tulsa, Mayo Hotel, April 22-25. Mr. R. H. Graham, 210 Plaza Court Bldg., Oklahoma City, Executive Secretary.

Southeastern Surgical Congress, Louisville, Ky., Brown Hotel, March 10-12. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S. E., Atlanta 3, Ga., Secretary.

Southwest Allergy Forum, Shreveport, La., March 31-April 1. Dr. Sim Hulsey, 505 Medical Arts Bldg., Fort Worth, Texas, Secretary.

Tennessee State Medical Association, Memphis, April 8-10. Dr. W. M. Hardy, 706 Church St., Nashville 3, Secretary.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National School Health Services Act

Representative Howell, Illinois, has introduced H. R 1980, a bill to provide for the general welfare by enabling the several states to make more adequate provision for the **health of school children** through the development of school health services for the prevention, diagnosis, and treatment of physical and mental defects and conditions The bill proposes to authorize an appropriation of $12,000,000 for the fiscal year commencing July 1, 1947, the sum of $18,000,000 for the next fiscal year and for each succeeding fiscal year such sums as may be necessary. These sums are to be made available, it is proposed, to enable the United States, through the Federal Security Agency, to cooperate with each state in carrying out the objectives of the legislation. A National *Advisory Committee on School Health Services will be created to consist* of twelve members appointed by the Federal Security Administrator on recommendation of the Chief of the Children's Bureau, the Commissioner of Education and the Surgeon General of the Public Health Service. *One half of the members will be selected from panels of at least five* names each submitted by representative national organizations and at least three members shall be doctors of medicine and at least one a doctor of dental surgery The Federal Security Administrator will be required to administer the legislation through the Children's Bureau, utilizing the services of the Office of Education in matters involving state education agencies and pertaining to the training and supervision of school personnel

Army Women's Medical Specialist Corps

A bill introduced by Representative Smith, Maine, H. R 1943, proposes to establish a **permanent Nurse Corps** of the Army and Navy and a **Women's Medical Specialist Corps** in the Army to consist of a Dietitian Section, a Physical Therapist Section, and an Occupational Therapist Section

Alcoholic Clinic

Representative Hebert, Louisiana, proposes by H R 496 to authorize the Commissioners of the District of Columbia to establish and equip a clinic in connection with either some existing hospital or with some correctional institution or other facility for the diagnosis, classification, hospitalization, confinement, treatment, and study of persons who are found to be **chronic alcoholics** by the courts of the District of Columbia.

Miscellaneous

A bill introduced by Representative Eberharter, Pennsylvania, H. R. 1992, proposes to give employees of religious, charitable, scientific, literary, and educational institutions the benefits of coverage under **the Social Security Act**, the Federal Unemployment Tax Act, and the Federal Insurance Contributions Act

H R 1950, introduced by Representative Larcade, Louisiana, contemplates that veterans pursuing educational and training courses in public institutions **shall receive the books, supplies, and other equipment** they would receive if they pursued similar courses in private institutions

A bill introduced by Representative Smith, Maine, as H. R. 1982, proposes to revise the **Medical Department of the Army.**

The establishment of a **veterans' hospital** in central Alaska is proposed by H R 1879, introduced by Representative Hagen, Minnesota

STATE LEGISLATION

Arizona

Bill Introduced.—H. 163 proposes to require each applicant for a ***marriage license** to present* a certificate signed by a duly licensed physician stating that the applicant is free from syphilis and other venereal diseases, tuberculosis and any other chronic or malignant infectious disease

California

Bills Introduced.—A. 1380, to amend the welfare and institutions code, proposes to provide space in existing mental hospitals for professional services to be rendered by **licensed chiropractors** only and proposes that all such professional services shall be consistent with the theory and principles of the science of chiropractic *A. 1481 proposes the enactment* of a **state hospital survey** and construction act requiring an inventory of existing hospital facilities and the development of a state plan for the construction of additional needed hospital facilities. The proposal would also require the appointment of an advisory hospital council and would authorize the state department of public health to apply for and accept federal funds granted for assistance in state hospital construction *A. 1500 and S 788 propose* the enactment of a **prepaid health service act.** A 1501, to amend the vehicle code, proposes to exempt from certain provisions thereof **surgeons and chiropractors** traveling in response to an emergency call Physicians are already exempt. A. 1582 proposes to require all persons ***employed as food handlers** to* obtain a certificate from the state board of public health stating that they are not infected with any communicable disease A. 1664, to amend the law relating to **premarital examinations**, proposes to authorize chiropractors to make the required examination. A. 1808, to amend the health and safety code, proposes that no district hospital shall provide by rule, regulation or by-law any **discrimination against a person** on account of race, creed or color or any discrimination which directly or indirectly would deny free choice of a physician or surgeon S 763, to amend the insurance code, proposes to authorize the formation of **medical and hospital service associations.** S 808, to amend the health and safety code, proposes to require every licensed physician and surgeon or other person engaged in prenatal care of a pregnant woman, or attending such woman at the time of delivery, to **obtain a blood *specimen of*** such woman at the time of the first professional visit or within ten days thereafter and to submit such sample to an approved laboratory for a laboratory test for syphilis

Connecticut

Bills Introduced.—*H. 436 proposes to appoint the state department of* health as the agency to administer **the hospital survey** and construction act H 550, to amend the medical practice act, proposes to grant the board discretion in accepting **licenses from other states in** lieu of examination H 551, to amend the law relating to the **practice of osteopathy** proposes to require certification by the board of healing arts of osteopathic national board diplomates applying for a license without examination H 553, relating to the **practice of osteopathy**, would require applicants for a license by reciprocity to meet the requirements of the state board of healing arts before being granted a license without examination H 552, to amend the **law relating to naturopathy**, proposes, among other things, to provide that a person who has been refused a certificate by the state board of healing arts does not qualify for a license without examination by the board of naturopathic examiners H 705, to amend the **law relating to chiropractic**, proposes that no person who has been refused a certificate by the state board of healing arts may qualify for a license without examination by the board of chiropractic examiners S 168 proposes to extend the scope of services to be rendered by district and special laboratories to the examinations of **supposed morbid tissues** and other types of work S 170 proposes to broaden the scope of activities of the **bacteriologic laboratory** so as to conform with those of a modern public health laboratory. S 173 proposes to clarify definitions of standards as applied to **clinical thermometers.** S 291 proposes an impartial study for the purpose of establishing a scientific method of **health insurance** for the state. S. 405 proposes that no hospital receiving state aid shall employ **at a fixed salary a physician** who would compete with outside physicians by having patients referred to the hospital for services rendered by such physician

Illinois

Bills Introduced.—H 13 proposes the enactment of a **hospital licensing** and inspecting law. H. 67, to amend the law relating to criminal jurisprudence, proposes to make it **unlawful to dispose of the barbiturates** except on prescription of a person licensed by law to prescribe and administer barbiturates or delivered by such person to his patient in the course of his professional practice.

Indiana

Bill Introduced.—S 212, to amend the medical practice act, proposes among other things to authorize the board of medical examiners to accept examinations certified by the **national board as the examination** given to the applicant This would enable an applicant to be licensed in Indiana without having to wait until the regular examination given *by the Indiana board occurs*

Bills Passed.—S 67 passed the senate February 11. It proposes the free distribution of **blood plasma** throughout the state, for use in the control of disease, to persons in need who are too poor to pay for it themselves S. 213 passed the senate February 14. It proposes the **annual registration** of all persons holding an unrevoked license to practice the healing art in any form or manner.

Massachusetts

Bills Introduced.—H. 641 and H 1446 propose the enactment of a Massachusetts **cash sickness compensation act.** H 1419 proposes a law requiring the **semiannual physical examination of all food handlers** to determine the presence or absence of tuberculosis or other communicable disease the examination to be made by the health officer or his aides. H 1416 proposes the enactment of a voluntary system for the payment of hospital, surgical operation, sickness and bodily injury and maternity **benefits to employees.** S. 356 proposes the appointment of a commission to conduct a study relative to the **setting up of a state university** with an established medical center located in or near Boston

Montana

Bills Introduced.—H. 353, to amend the law relating to nonprofit corporations, specifically authorizes **the organization of corporations for** the purpose of defraying or assuming the cost of professional services, including services rendered by doctors of medicine or other professional licentiates recognized by the laws of the state of Montana, and/or services rendered by hospitals, health centers, clinics or sanatoriums S 100 proposes that each applicant for a **marriage license** shall present a certificate signed by a duly qualified physician licensed to practice medicine and surgery in any state or territory of the United States certifying that the applicant has been given an examination for the discovery of syphilis

Nebraska

Bills Introduced—Bill No 250 *proposes to provide for* the licensing, inspection and regulation of **hospitals** and related institutions within the state and to create a hospital licensing council. Bill No. 300 proposes to require **restaurant owners** to display a certificate from a licensed physician certifying that no person employed in such restaurant is affected with certain named diseases Bill No 541 proposes the appointment of a **state health committee** to advise with the governor on candidates for the office of director of health and to advise with the director on general policies affecting public health. Bill No. 380, to amend the medical practice act, proposes to **include an osteopath** on the board of medical examiners. Bill No. 408, to amend the section of the medical practice act referring to examinations, proposes to **exempt chiropractors therefrom.**

New Hampshire

Bills Introduced.—H. 206 proposes the enactment of a **compulsory sickness benefit plan.** H. 337, to amend the law relating to the practice of medicine, proposes to authorize the board to **register and license without examination** any applicant legally qualified to treat human ailments or practice medicine in any other state and who is honorably discharged from the armed forces if such veteran meets the requirements of section 10 and was engaged in the active practice of medicine in the armed forces, provided that licenses under this section shall be granted only to applicants who take up their residences in the state and shall expire on their removal from the state, and provided further that the provisions of the proposal would expire three years after the date of passage.

New Jersey

Bills Introduced.—A. 88, to amend the medical practice act relating to the requirement of **two years' internship,** proposes that in lieu thereof an applicant may serve one year of internship in an approved hospital plus one year's professional experience while a member of the Army, Navy or Public Health Service of the United States. A. 97, to amend the workmen's compensation act, proposes that an injured workman shall have the **right to select the physician,** surgeon or dentist by whom, and the hospital in which, he desires to be treated.

New Mexico

Bills Introduced.—S. 80, to amend the law relating to **osteopathic physicians,** proposes to eliminate therefrom the requirement that no plan for rendering medical services shall be adopted by any state, district, county, city or town which discriminates against osteopathic physicians and surgeons. S. 112, to amend the medical practice act relating to **the definition of "practice of medicine,"** proposes to add the phrase "or perform any act, the results of which shall be used for diagnosis." S. 115 proposes the creation of a state board of naturopathic examiners and defines naturopathy as follows: **"The term 'Naturopathy'** as used herein shall comprehend, embrace and be composed of the following named acts, practices and usages, as set forth in the Act of Congress of the United States, enacted February 7, 1931, H. R. 12169 defining Naturopathy. Diagnosis, and Practice of physiological and mechanotherapy, articular manipulation, corrective orthomaterial sciences of healing as follows,—The physiological and mechanical sciences such as pedic gymnastics, neurotherapy, psychotherapy, hydrotherapy, phototherapy, chromotherapy, vibrotherapy, thalmotherapy, and dietetics which shall include the use of foods of such biochemical tissue-building products and cell salts as are found in the normal body; and the use of vegetal oils and dehydrated and pulverized fruits, flowers, seeds, barks, herbs, roots and vegetables uncompounded and in their natural state."

New York

Bills Introduced.—A. 1234 and S. 1026 propose that no person shall be required to submit to a **physical examination** as a condition of securing employment. A. 1259, to amend the labor law, proposes the enactment of a **disability benefit law.** A. 1283, to amend the education law with respect to the definition of the practice of medicine, proposes to limit the **practice of x-ray** diagnosis, x-ray therapy or radium therapy as defined in the proposal to persons licensed to practice medicine. A. 1299, to amend the education law, proposes the creation of a board of **medical technologist examiners** and defines medical technologists and clinical laboratory technicians. A. 1395, to amend the education law, proposes that a license to practice **optometry** shall not permit the holder thereof to fit contact lenses except under the supervision of a duly licensed physician.

Bill Passed.—S. 167 passed the House February 17. To amend the law relating to the practice of **midwifery,** it proposes that as a condition to annual renewal of a license an applicant must submit evidence that she has attended and conducted one or more deliveries during the twelve months last passed.

North Dakota

Bills Introduced.—H. 127 proposes regulations for the licensing of **chiropractic hospitals** by the state board of chiropractic examiners. S. 237 proposes a law for the licensing, inspecting and regulating of hospitals in the state and for the appointment of a **hospital advisory council** to assist in the preparation of rules, regulations and standards for the licensing of hospitals.

Oklahoma

Bills Introduced.—H. 159 proposes to require various practitioners of the healing art to list **descriptive letters after their names** in order to designate the branch of practice in which they engage. S. 76 proposes to require prospective teachers to have **a medical examination** for the purpose of determining mental and physical qualifications, the mental and physical examination to be made by a physician authorized to practice medicine. S. 111, to amend the medical practice art relating to the requirement of **one year's internship** as a prerequisite to examination, proposes to require further that all applicants shall have served an internship of at least three months in one of the state hospitals for the insane or feebleminded.

Tennessee

Bill Enacted.—H. 234 has become chapter 9 of the Public Acts of 1947. It creates a **state licensing board** for the healing arts and defines healing art as "offering or undertaking to diagnose, treat, operate on, or prescribe for any human pain, injury, disease, deformity, or physical or mental condition." A person who desires to practice any specific branch of the healing art in Tennessee will now be required to obtain a license from this board after the applicant has passed the specific examination required of the specific examining board in the state.

Texas

Bills Introduced.—H. 217 (same as S. 161) proposes, among other things, that any physician duly licensed under the laws of Texas to practice medicine who, when an autopsy is ordered by a justice of the peace, **performs the autopsy** in good faith in the belief that the order of the autopsy is a valid order, shall not be held liable for damages in the event it should be determined that the order of autopsy made by the justice of the peace was for any reason invalid. S. 190, to amend the medical practice act, proposes to exempt therefrom persons who practice **physiotherapy** and confine their practice strictly to nonmedical treatment by electricity, massage and exercise and dietotherapy when confined to the regulation of diet and the use of food supplements.

Utah

Bills Introduced.—H. 216 proposes that an **optometrist** may be accepted in court as an expert witness on testimony relative to the diagnosis of the human eye and its appendages or any visual, muscular, neurologic or anatomic anomalies of the human eye and their appendages. S. 177, to amend the **premarital examination law,** proposes to authorize the required examination to be made by a licensed osteopathic physician and surgeon.

Vermont

Bills Introduced.—H. 75 proposes to repeal the existing medical practice act and to enact a new law for the **licensing of physicians, osteopaths and chiropractors.** H. 148 proposes an appropriation for the purpose of purchasing and maintaining **mobile health units** to be used by the state board of health in making medical, dental and psychiatric examination, of school children. H. 154 proposes to authorize the superintendent or managing officer of the Vermont state hospital to **cause an autopsy to be performed** on the body of any person who dies while a patient at such institution, the purpose of the proposal being to increase the knowledge of the causes of nervous and mental disorders and mental deficiencies.

Washington

Bills Introduced.—S. 158 proposes the creation of a **medical disciplinary board** to hear complaints for the revocation of professional licenses. S. 173 proposes the enactment of a **hospital survey and construction act** requiring a survey of hospital facilities in the state and the preparation of a plan for the construction of needed additional facilities. The proposal would require the appointment of an advisory hospital council and would authorize general collaboration with the federal government relative to the acceptance and expenditure of federal funds. S. 193 proposes the creation of a **sanipractic physicians' examining board** and defines sanipractic as "the science and art of applied prophylactic and therapeutic sanitation, which enables the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercises active and passive, manipulation, adjusting tissue, vital organs or anatomical structure by manual, mechanical or electrical instruments or appliances; or other natural agency, to assist nature restore a psychological and physiological interfunction for the purpose of maintaining a normal state of health in mind and body."

West Virginia

Bill Passed.—H. 9 passed the house January 31. To amend the medical practice act, it proposes to exempt therefrom the practice of **the religious tenets of any church** in the ministration to the sick or suffering by mental or spiritual means, provided sanitary and public health laws are complied with, no practices are used which may be dangerous or detrimental to life or health and no person is denied the benefits of accepted medical and surgical practices.

Wisconsin

Bills Introduced.—A. 161 proposes the appointment of a state board of **examiners in naturopathy** and defines naturopathy as "the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the material methods or agencies of healing as taught by approved schools of naturopathy, said methods or agencies including dietetics, phytotherapy, vitamin or mineral or glandular food supplementations, irrigations, inhalations, external applications, physiotherapy and electrotherapy. The practice of naturopathy shall exclude the practice of medicine, surgery, obstetrics, osteopathy, chiropractic and the use of drugs. The practice of naturopathy shall exclude the treatment of cancer, tuberculosis, gonorrhea, syphilis, diphtheria, scarlet fever, typhoid fever, smallpox and fracture." S. 156, to amend the law relating to the **licensing of osteopaths,** proposes to require applicants for a license to practice osteopathy to have completed at least 12 months' internship in a reputable osteopathic hospital or its equivalent. S. 162 proposes to require all physicians to report immediately to the local health officer the name, age and address of every person diagnosed as afflicted with epilepsy or similar disorders characterized by lapses of consciousness. S. 170 proposes the creation of a mental health authority and the creation of a **state mental health commission.**

Wyoming

Bills Introduced.—S. 73 proposes the enactment of a state **hospital survey and construction act** requiring an inventory of existing hospitals and the development of a program for the construction of additional necessary hospital facilities. The proposal would also require the appointment of an advisory hospital council and provide for collaboration with the federal government in the application for and acceptance of federal funds to assist in hospital survey or construction within the state. S. 78 proposes the creation of a **medical practice act** for osteopathic physicians and surgeons. Under the terms of this proposal osteopathy means "a complete school of medicine and surgery based upon fundamental principals, some of which are different, in emphasis, from some of the principals as taught by other schools of medicine."

GOVERNMENT SERVICES

ARMY

ARMY AWARDS AND COMMENDATIONS

Brigadier General Charles B. Spruit

The Distinguished Service Medal has been awarded to Brig. Gen. Charles B. Spruit, U. S. Army, of Washington, D. C. Among his services the citation mentions these: As surgeon, United Kingdom Base, he performed meritorious and distinguished service in England from September 1944 to May 1945. In organizing and supervising operation of the medical units he divided them into seven geographic groups and assured the proper delineation of the functions and responsibility of the group hospitals. He implemented the plans for specialty hospitals to care for special types of cases and, by his own stimulating leadership, welded all the group staffs and his own staff into an efficient and smoothly working organization. Through his knowledge of the medical service and its operational requirements and by his exceptional organizational ability, General Spruit led the United Kingdom Base Medical Service to the attainment of its outstanding accomplishments. Dr. Spruit graduated from Harvard Medical School in 1915 and entered active military service in 1917.

Colonel Charles L. Baird

The Legion of Merit was recently awarded to Col. Charles L. Baird, M. C., U. S. Army, of Philadelphia for exceptionally meritorious conduct in the performance of outstanding services as commanding officer of the Fifth Evacuation Hospital from Dec. 17, 1943 to Feb. 28, 1945 in England, France, Belgium and Germany. The citation states that Colonel Baird labored for long periods of time in the organization, training and operation of his hospital to the end that it would give medical treatment of a high standard to patients. He constantly strove for additional improvements within his command. With no previous combat experience, and in spite of difficult conditions incident to the invasion, the hospital, under his capable supervision and direction, treated more than 18,000 casualties with the highest degree of efficiency. Colonel Baird's able leadership, astute judgment and professional wisdom were instrumental in the saving of many lives and the alleviation of much suffering. Dr. Baird graduated from the Medical College of Virginia in 1929 and entered the service July 1, 1930.

Colonel Leonard D. Heaton

The second Oak Leaf Cluster to the Legion of Merit has been awarded to Col. Leonard D. Heaton, M. C., U. S. Army, for performing exceptionally meritorious services as commanding officer of the 802d Hospital Center from November 1944 to June 1945. The citation recounts that by his unusual organizational ability he established many widely separated medical units in England into a closely knit and highly efficient hospital center. By his forceful leadership he ably directed a highly complex operation to outstanding success. Dr. Heaton graduated from the University of Louisville, Ky., in 1926 and entered the military service on Aug. 1, 1926.

Lieutenant Colonel Charles W. Elkins

The Legion of Merit was recently awarded to Lieut. Col. Charles W. Elkins, M. C., A. U. S., of Cleveland, who was chief, neurosurgical section, Newton D. Baker General Hospital, Martinsburg, W. Va., from September 1944 to December 1945. Lieutenant Colonel Elkins achieved an outstanding record in the rehabilitation of paraplegic patients. In addition to his brilliant surgery, states the citation, his contribution to the dissemination of knowledge and skill in his field will be of lasting peacetime benefit. Dr. Elkins graduated from Western Reserve University School of Medicine in 1937 and entered the service Jan. 15, 1942.

Lieutenant Colonel Richard H. Meade

The Legion of Merit has been awarded to Lieut. Col. Richard H. Meade, M. C., A. U. S., of Chicago, who distinguished himself as chief of the thoracic surgery section in the Kennedy General Hospital, Memphis, Tenn., from February 1943 to December 1945. His achievements were stated in the citation to reflect unusual surgical skill, high qualities of leadership and unselfish devotion to the care and treatment of the sick and wounded. Dr. Meade graduated from Harvard Medical School in 1921 and entered the military service on May 16, 1942.

Captain John E. Lamy

The Silver Star has been awarded to Capt. John E. Lamy, M. C., A. U. S., of Kansas City, Mo., who on April 6, 1942 displayed gallantry in action on Bataan, Philippine Islands, as surgeon for the Third Battalion, 57th Infantry (PS). While in bivouac, says the citation, the battalion was subjected to exceptionally heavy attack by enemy dive bombers and artillery fire, and casualties were heavy. Captain Lamy suffered an eye injury from a bomb fragment, but despite his injury and the fury of the air attack he provided medical aid to the wounded as they were brought to the aid station. Dr. Lamy graduated from McGill University Medical School in 1937 and entered the military service in September 1940.

Captain Arthur L. Abbett

The Bronze Star Medal was recently awarded to Capt. Arthur L. Abbett, M. C., U. S. Army, of San Leandro, Calif., for meritorious achievement in connection with military operations against the enemy at Bougainville, Solomon Islands, on April 16, 1944. The citation gives further details: During the attack on Hill 500, because of the intensity of enemy fire, more casualties were sustained than the litter teams could efficiently handle. Under intense enemy machine gun, mortar and rifle fire Captain Abbett, a battalion surgeon, with complete disregard for his own personal safety, went forward to the front line to supervise and assist in the recovery of wounded men. His presence on the front line and his action in aiding the wounded were of great value to the morale and fighting efficiency of the troops. Dr. Abbett graduated from the University of Minnesota School of Medicine in 1936 and entered the service Jan. 3, 1942.

Captain Jack A. Comstock

The Bronze Star Medal has been awarded to Capt. Jack A. Comstock, M. C., A. U. S., of Roswell, N. M., formerly of Boulder, Colo., who, as assistant receiving and evacuation officer at General Hospital Number Two, Bataan, rendered meritorious service from Jan. 1 to April 9, 1942. The citation credits him with working long hours and exercising a skilful and sympathetic handling of the sick and wounded. Through his outstanding professional ability and resourcefulness, Captain Comstock contributed greatly, under extreme difficulties and with limited supplies, to the medical care of patients. Dr. Comstock graduated from the University of Colorado School of Medicine in 1938 and entered military service Jan. 27, 1941.

Captain Karl Pickard

The Bronze Star Medal has been awarded to Capt. Karl Pickard, M. C., A. U. S., of Brooklyn, who, according to the citation, performed meritorious service in England from December 1943 to March 1945. As venereal disease control officer, in addition to his assigned duties as chief of medicine, Tenth General Dispensary, Captain Pickard by his untiring efforts, ingenuity and leadership made a substantial contribution to the success of the medical mission in the European Theater of Operations. Dr. Pickard graduated from Long Island College of Medicine in 1935 and entered the military service July 10, 1940.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, *new hospitals, education and public health.*)

CALIFORNIA

Grant for Cancer Research.—The University of California Medical School, Berkeley-San Francisco, will receive a bequest valued at $59,206 to carry on research for a cure of cancer made possible by a grant from the estate of the late Albert C. Hooper, Palo Alto philanthropist.

New Hospital for Orange County.—The site for a new hospital to be built by the Presbyterian Hospital Association of Orange County has been secured near Costa Mesa, overlooking Newport Harbor. The hospital will serve patients of the coast area and half of Orange County, thus relieving the overburdened hospital facilities. The half million dollar goal set up by the board of directors has already been subscribed.

Clinic for Poliomyelitis Patients.—Los Angeles County Hospital early this summer will open a complete clinic for the treatment of poliomyelitis patients. Heading the clinic is Dr. O. Leonard Huddleston, director, department of physical medicine of the University of Southern California Medical School, Los Angeles, who directed poliomyelitis treatments at the U. S. Army Fitzsimons General Hospital, Denver, during the war. Los Angeles County furnishes the space, maintenance and most of the personnel, while the research laboratory will come from the university and the foundation, according to Leroy R. Bruce, director of the hospital.

California Society of Internal Medicine.—The California Society of Internal Medicine, organized in San Francisco last July, now has 350 members. A member must be a doctor of medicine licensed to practice in California and either a specialist certified by the American Board of Internal Medicine or a practitioner in internal medicine exclusively for a period of at least five years, and he must have the approval of the council. The affairs of the society are administered by a council of nine active members with Drs. William L. Bender, San Francisco, president and DeWitt K. Burnham secretary-treasurer. The address of the society is 2180 Washington Street, San Francisco 9.

CONNECTICUT

Survey of Rural Health.—The State Medical Society's rural health committee, Dr. Norman H. Gardner, East Hampton, chairman, is conducting a statewide survey aimed toward improving health facilities and service in smaller towns and villages. Other members of the committee include Drs. Gert S. Gudernatsch, Sharon; David H. Bates, Putnam, and William H. Upson, Suffield.

Rh Blood Typing.—The Public Health Committee of the Connecticut State Medical Society recently reaffirmed its stand favoring laboratory analyses by the state department of health for discovery of cases in which the Rh factor is lacking in antepartum blood specimens. The original proposal was made by the committee in 1944. In a lengthy survey of the need for such typing service, Friend Lee Mickle, Sc.D., head of the Bureau of Laboratories of the state department of health, has declared that "the insistent demands for Rh typing service cannot be much longer ignored; they must be met by the state department of health, or some other solution satisfactory to the practitioners must be speedily forthcoming from the medical profession." Annual cost of the service is estimated at $12,000.

School of Alcohol Studies. — The Summer School of Alcohol Studies, conducted by the Laboratory of Applied Physiology of Yale University, will hold its fifth annual session July 6-31. The curriculum deals with the medical and various other aspects of alcohol problems. The school is under the directorship of Professor Elvin M. Jellinek, Sc.D. The list of lecturers is made up of authorities who have carried out original research in their respective fields, and, though mainly from the faculties of Yale University, includes representatives of other national institutions. Applications for admission and scholarships to the 1947 course will be received up to April 15, 1947. A prospectus may be obtained by writing to the Executive Secretary, Summer School of Alcohol Studies, Yale University, New Haven, Conn.

DISTRICT OF COLUMBIA

Dr. Geschickter Appointed Professor of Pathology.—Dr. Charles F. Geschickter, Baltimore, has been named professor of pathology and parasitology and director of the department of Georgetown University School of Medicine, Washington. Dr. Geschickter, a graduate of Johns Hopkins University School of Medicine, Baltimore, was director of the Cancer Research Laboratory at Johns Hopkins University School of Medicine, Baltimore, from 1929 to 1940 and is the author of "Tumors of the Bone," published in 1932.

ILLINOIS

Personal.—Dr. J. P. Schreiter, Savanna, was recently honored at a dinner given by the Savanna City Hospital staff. A graduate of Rush Medical College, Chicago, Dr. Schreiter has served forty-six successive years as Carroll County coroner and also company physician and surgeon for the Milwaukee and Burlington railroads.

Cancer Diagnostic Clinic.—A cancer diagnostic clinic was established at Marshall Browning Hospital, DeQuoin, in December with Drs. Hollis N. Allen, St. Louis, and Charles E. Bell, East St. Louis, in charge. The clinic is intended to serve all of southern Illinois and is in session at 7 p. m. on the first and third Wednesdays of each month. The state department of health furnished the x-ray and laboratory equipment. Plans for the county service were announced by the state department more than five years ago, but the war delayed its establishment.

Society at Prewar Strength. — The Winnebago County Medical Society announced at its last annual meeting that it had returned to prewar strength with a membership of 174, or 1 doctor for every 770 persons, almost double the low point reached during the war, when there were about 100 civilian practitioners, or 1 doctor for every 1,340 residents. Dr. Joseph C. Rheingold, Rockford, presented a paper, "Use of Sodium-Pentothal as a Truth Serum," and Dr. Charles B. McIntosh, Iowa City, discussed "Treatment of Hyperthyroidism in Children." Officers elected at the meeting are Drs. Charles L. Leonard, president; Alexander Braze, vice president, and William H. Palmer, secretary-treasurer, all of Rockford.

Herrick House for Convalescent Children.—Total reconditioning is the theme of the new program of Herrick House at Bartlett, Ill., a convalescent home for children with hearts crippled by rheumatic fever. Doctors, nurses, social workers, teachers, psychiatrists and counselors assist in working out the problems of these children. Named in honor of Dr. James B. Herrick of Chicago, this convalescent home, conducted by the Sunset Camp Service League, is open the year round. In winter 40 convalescent boys and girls from 8 to 14 years of age, and in late spring 15 additional children, can be accommodated. The main building has school rooms, library, laboratory, x-ray room, doctor's offices, resident's room, dining room and shop. One wing houses the infirmary and nurses' quarters, another the boys in two dormitories with large living room and counselors' rooms; a third wing, with two dormitories and play space, houses the girls. The attending physician, Dr. Richard L. Marks, Park Ridge, is a member of the staff of Children's Memorial Hospital, Chicago. Herrick House takes in children with rheumatic fever as soon as the acute phase is past. The objective is to rehabilitate and return them to normal living as much as possible. The Sunset Camp Service League also conducts the Max Straus Summer Camp at Bartlett. The Chicago office at 343 South Dearborn Street is in charge of Mrs. Edwin Eells. Mrs. Sidney L. Schwarz, Highland Park, Ill., is president of the league. The honorary chairman of the Medical Advisory Committee of 13 members is Dr. Herrick. The board of directors has 26 members.

Chicago

Institute of Medicine. — The March programs for the fellows of the Institute of Medicine in the current series "Where We Stand Today in Medicine" are March 14, "Nerve Regeneration," by Paul A. Weiss, Ph.D., professor of zoology, University of Chicago School of Medicine; March 28, "Ulcerative Colitis," Dr. Walter L. Palmer, professor of medicine, University of Chicago School of Medicine.

Symposium on Medicolegal Problems.—The fifth and final meeting of the symposium on medicolegal problems of the Institute of Medicine of Chicago will be held March 4 at 7:30 at the Chicago Bar Association. The medical and legal aspects of radiation hazards and health protection in radioactive research will be presented by Dr. Austin M. Brues, associate professor of medicine, University of Chicago School of Medicine, and Augustine J. Bowe, Esq., Chicago Bar Association, with Royal W. Irwin, Chicago Bar Association, presiding.

Capps Prize Awarded to Dr. Block.—The Institute of Medicine of Chicago announces that the $400 1946 Joseph A. Capps Prize for Medical Research has been awarded to Dr. Matthew Block, Brooklyn, for his work on "Sequelae of Trench Foot: Anatomic Study." The Joseph A. Capps prize is awarded for the most meritorious investigation in medicine or in the specialties of medicine or in the fundamental sciences, provided the work has a definite bearing on some medical problem. Dr. Block received his M.D. degree in 1943 from the University of Chicago Department of Medicine.

Nineteen Northwestern Faculty Members Retire.—At a dinner and reception given by the Northwestern University Alumni Association February 13, 19 members of the Medical School faculty of Northwestern University were honored on the occasion of their retirement. They will henceforth hold emeritus rank: Drs. Archibald Church, now of Pasadena, Calif., Hans C. S. Aron, James G. Carr, William C. Danforth, Evanston, Alexander A. Goldsmith, Mark T. Goldstine, Christian D. Hauch, Willard G. Jeffries, Anna R. Lapham, Hugh McKenna, Malcolm T. MacEachern, Julius F. Meyer, Harry E. Mock, Otto Porges, Harry M. Richter, Louis E. Schmidt, James P. Simonds, John G. Wilson and John A. Wolfer. The twentieth special guest was Dr. Andrew C. Ivy, who resigned from the Northwestern faculty of medicine last fall to become vice president in charge of professional schools of the University of Illinois.

Tuberculosis Control Program.—The Tuberculosis Control Committee in its report to the Council of the Chicago Medical Society on January 14 pointed out that the tuberculosis rate for Illinois is 45 plus per hundred thousand and for Chicago it is 58 plus, while in neighboring Iowa it is 15 plus. During the last decade the mortality rate for the county has fallen 35 per cent, in Chicago 10 per cent. Among Chicago's nonwhite men past 60 the rate is 435 plus per hundred thousand. To control tuberculosis Illinois spends 42 cents for each tuberculosis death as compared to the average of $309 of various other states. In addition, Illinois and Nevada are the only states that do not have state owned and operated sanatoriums. The proposed program for control of tuberculosis includes recommendations for the construction of four 250 bed sanatoriums, conversion of the Municipal Contagious Hospital for the care of tuberculosis, a tax supported tuberculosis control program for Cook County outside Chicago, construction of three 150 bed sanatoriums on the north, west and south sides of Chicago and encouraging private sanatoriums to increase their beds to provide for tuberculous patients. The construction program would require about $45,000,000, according to Dr. James H. Hutton, co-chairman of the tuberculosis control committee. New legislation is being sought to carry out the program. The aid of 125 organizations has been enlisted for a program of public education. Members of the tuberculosis control committee are Drs. Hutton, Jerome Head, Edward A. Piszczek, Arthur W. Newitt and Oscar Hawkinson and Arthur H. Parmelee of Oak Park, Frederick W. Slobe, Henry C. Sweany and Clarence L. Wheaton.

MASSACHUSETTS

Sharp Increase in Diphtheria and Measles.—The annual report of the state department of public health showed what it characterized as a "most alarming experience" in the sharp rise in diphtheria, which more than doubled its incidence for any year since 1937 with a total of 443 reported cases as against 194 for 1945. Boston, Somerville, Lowell, Lynn, New Bedford, Taunton, Worcester and Gloucester were listed as having high prevalence. Measles broke all records during 1946. Ordinary measles cases jumped from 7,486 in 1945 to 38,402 in 1946, while the German variety jumped from 1,308 to 4,619.

NEW YORK

Dr. Birkhaug to Set Up BCG Program.—The tuberculosis control program of the state health department calls for the manufacture and use of the BCG vaccine, Dr. Robert E. Plunkett, Albany, assistant health commissioner, has announced. Dr. Konrad Birkhaug, Albany, formerly of Norway, has been engaged to set up the program for the development of the vaccine and is now working under the direction of Dr. Gilbert Dalldorf in the division of laboratories and research, Albany. Plans for the distribution of vaccine are being developed jointly by the medical education and public health committee of the Medical Society of the State of New York and the state health department, Dr. Plunkett said. A limited number of physicians are to be trained in its use. This is part of the state's $20,000,000 twenty year plan to eradicate tuberculosis, proclaimed by the governor last year.

New York City

Child Development Center.—A clinic for the treatment of children with emotional disturbances opened February 3 at 227 East 59th Street, to be known as the Council Child Development Center. It is supported jointly by the New York section, National Council of Jewish Women, the Lieut. Lester N. Hofheimer Estate and the Jewish Board of Guardians. Employing the service of pediatricians, psychiatrists, nursery teachers and other specialists, it seeks to discover the causes of behavior problems in apparently normal children.

Study of Eye Diseases.—Four scholarships of $500 each for advanced study of eye diseases at the New York University College of Medicine have been awarded to Drs. Edward Danforth, Bainbridge; Charles P. Goldsmith, Catasauqua, Pa.; Jonathan L. Hanis, Elberon, N. J., and Hugh E. McGhee, Jeffersonville, all postgraduate students in the department of ophthalmology. The Eye Conservation Fund, Inc., of the New York Lions Club, Ernest R. Fryxell, chairman, initiated the scholarships last spring with a gift of $2,000 to the college.

Increase in Venereal Disease.—New York City and state had a sharp increase in venereal disease in 1946, according to Dr. Israel Weinstein, health commissioner. A study of reported cases, with particular emphasis on the ages of the infected persons, indicates a disproportionate increase in the teen age groups. Upstate New York in 1946 reported double the number of 1945 cases of early infectious syphilis and approximately three times as many as the prewar monthly average. In New York City there has been a steadily increasing number of infections since 1941.

Psychiatric Pavilion Opened.—The new seven story psychiatric pavilion of Kings County Hospital in Brooklyn opened February 6, when 112 male patients were transferred from the old psychiatric pavilion. The new pavilion has a capacity of 400 beds with four wards on each floor from the second to the sixth which are arranged as either private or semiprivate rooms, eliminating the use of large wards. The seventh floor contains equipment for occupational therapy, classrooms and space for exercising patients. Dr. Sam Parker, director of the psychiatric division at the hospital and also director of psychiatry of the New York City Department of Health, said the new pavilion will offer "a planned degree of individualized treatment of patients which does not exist in any other public hospital." It will also relieve the heavy load on the psychiatric service in Bellevue Hospital. Women and children from Queens and Brooklyn will also be admitted.

OHIO

Society News.—At a recent meeting of the Cincinnati Academy of Medicine Dr. Edgar V. Allen, Mayo Clinic, Rochester, Minn., spoke on "The Present Status of Anticoagulant Therapy."

Personal.—Dr. Harold C. Wise, Cleveland, has been appointed chief of staff at St. Anne's Maternity Hospital, succeeding Dr. Joseph R. Thompson, who died suddenly last December 22. Dr. Wise is a graduate of Creighton University School of Medicine, Omaha, and has been house physician at St. Anne's.——Enrique E. Ecker, Ph.D., professor of immunology, Western Reserve University, has been elected Councilor of Honor in the National Council of Scientific Investigations of Spain. Dr. Ecker recently returned from a trip to Europe, where he delivered a series of lectures.

OREGON

Postgraduate Course in Ophthalmology and Otolaryngology.—Lectures, clinical demonstrations and ward rounds have been planned for the eighth annual spring Postgraduate Course in Ophthalmology and Otolaryngology to be held in Portland, April 7-12. The program has been arranged by the Oregon Academy of Ophthalmology and Otolaryngology and the University of Oregon Medical School, Portland. Drs. John H. Dunnington, professor of ophthalmology at Columbia University College of Physicians and Surgeons, New York, and George E. Shambaugh Jr., assistant professor of otolaryngology, Northwestern University Medical School, Chicago, are among the guest speakers.

TENNESSEE

Unveil Plaque at Jackson.—A bronze plaque to the late Dr. James W. McClaran recently was unveiled at Memorial Hospital, Jackson. Dr. McClaran, a native of Jackson and a graduate of the Vanderbilt University School of Medicine, Nashville, who distinguished himself as a surgeon attached to the French army and later to the U. S. Army in World War I, was a member of the Memorial Hospital staff for years until his death in December 1945.

TEXAS

Pathologists Meet.—The Texas Society of Pathologists had its annual meeting January 26 at Houston. The morning was devoted to a business session, and in the afternoon a seminar on microscopic pathology was held at the Baylor University College of Medicine with Dr. Stuart A. Wallace, Houston, in charge. Newly elected officers for 1947 are Drs. David A. Todd, San Antonio, president; William W. Coulter, Houston, president-elect; John F. Pilcher, Corpus Christi, vice president, and Charles T. Ashworth, Dallas, secretary-treasurer. The next meeting will be held Jan. 25, 1948 at Galveston.

Pediatric Conference.—The spring pediatric conference of the Postgraduate Division of the University of Texas School of Medicine, Galveston, has been announced for March 31 through April 5. It is a cooperative undertaking by the University of Texas Child Health Program and the Division of Maternal and Child Health of the Texas State Board of Health. A limit of sixty physicians will be accepted. Registrants on state or federal payrolls will receive expenses in accordance with state regulations. Guest speakers for the session include Drs. John M. Adams, associate professor of pediatrics, University of Minnesota Medical School, Minneapolis; Harry H. Boyle, associate of pediatrics, Northwestern University Medical School, and associate attending pediatrician, Children's Memorial Hospital, Chicago; Hugh McCulloch, associate professor, clinical pediatrics, Washington University School of Medicine, St. Louis; William A. Reilly, assistant clinical professor of pediatrics, University of California Medical School, Berkeley-San Francisco, and Philip M. Stimson, director of polio division, Knickerbocker Hospital, associate clinical professor of pediatrics, Cornell University School of Medicine, New York.

VERMONT

Medical Public Relations Plan.—The council of the Vermont State Medical Society has directed the executive secretary to prepare a coordinated public relations plan with a detailed outline for the integration of various technics. Intended for use primarily by the council, the plan will be available to all members.

VIRGINIA

Personal.—Dr. Thomas M. Peery, director of laboratories, Alexandria Hospital, Alexandria, Va., resigned in January to assume the post of director of laboratories at George Washington University, Washington, D. C.

New Health Services.—Effective February 1, Charles City County and New Kent County were added to the Peninsula Health District with offices in Charles City and Providence Forge, respectively. Dr. Thomas F. McGough Jr. is health officer for the district, with headquarters in Hilton Village. The Amelia-Goochland-Powhatan Health District has been established with headquarters at Powhatan, with Dr. Henry M. Snead as health officer.

PUERTO RICO

Nonimmigrant Entry Authorized for Doctors.—The Bureau of Immigration and Naturalization in Washington has authorized the entry into Puerto Rico as nonimmigrants of doctors who are not citizens of the United States to help alleviate the critical shortage of physicians on this island. The decision applies only to medical personnel who will fill vacancies in the Puerto Rican department of health for which qualified Puerto Rican personnel is not available.

Annual Meeting of Medical Association.—Physicians from Puerto Rico, continental United States and other American republics met in San Juan in December for a series of discussions and clinics marking the forty-third annual convention of the Medical Association of Puerto Rico. The guests of honor included Drs. William S. Middleton, dean, University of Wisconsin Medical School, Madison; James H. Means, professor of clinical medicine, Harvard Medical School, Boston; Leland E. Hinsie, professor of psychiatry, Columbia University College of Physicians and Surgeons, New York; Lyndon E. Lee Jr., University of Michigan Medical School; William A. Sodeman, professor of preventive medicine, Tulane University of Louisiana School of Medicine, New Orleans; Justus B. Rice, director of medical research, Winthrop Laboratories, New York City; Frederick F. Yonkman, director of research, the Ciba Laboratories, Madison, N. J.; Rodolfor Perez de los Reyes, Cuban cardiologist; Dr. Augustus Castellanos, professor of pediatrics, University of Havana, and Isaac Costero, pathologist, National Institute of Cardiology, Mexico City.

GENERAL

American College of Surgeons Sectional Meetings.—The American College of Surgeons will begin its 1947 series of two day sectional meetings in Baltimore with headquarters at the Lord Baltimore Hotel, March 10 and 11. The meetings are for the medical profession at large and for hospital personnel.

Visiting Scientist Returns to Moscow.—Professor Vassily V. Parin, secretary general of the Academy of Medical Scientists of the Union of Soviet Socialist Republics, returned to Moscow January 17 after a three month tour of the United States. He studied American medical education, medical research and public health procedures. Cancer comprised one of his chief studies here, he said.

Industrial Medicine Fellowship.—A fellowship in industrial medicine has been established at the University of Pittsburgh School of Medicine by Schenley Distillers Corporation. The fellowship carries a residency of eighteen months at the school of medicine. Further particulars may be had by writing to the Director, Department of Industrial Hygiene, University of Pittsburgh School of Medicine, Pittsburgh 13.

American Urological Association.—The annual meeting of the Mid-Atlantic Section of the American Urological Association will be held in Washington, D. C., March 20-22 at the Statler Hotel. Principal speakers will be Drs. Charles McMartin, Omaha, president, American Urological Association; E. Granville G. Crabtree, Boston, president-elect, and Ralph M. LeComte, Washington, president, Mid-Atlantic Section of the association.

Red Cross Drive.—This month the American Red Cross will appeal to the public for $60,000,000, a much lower goal than that of recent years. The Red Cross must maintain a staff for the armed forces wherever stationed and in the home towns of their families. Its 3,754 chapters cover every square mile of the nation. Estimated cost of carrying on the particular program as liaison between servicemen and their families is $6,018,000; for recreation for servicemen overseas, $11,987,000; for hospitals, domestic, $3,207,000; overseas, $2,037,000; veterans' hospitals, $1,893,000; for assistance to veterans and their families $2,249,000; home service, $25,561,000; disaster relief, $2,700,000; general executive administration, $1,558,000, and rebuilding overseas Red Cross organizations, $2,294,000. Fund chairman of the 1947-1948 drive for his second year is Harvey D. Gibson, an American Red Cross commissioner to Europe in both world wars.

UNRRA Health Division Closes.—The UNRRA Health Division will wind up its activities March 31 after more than three years of work. During this time UNRRA has made available to the health departments of thirteen liberated countries the advice and assistance of its international health staff and has given medical and sanitation services to over a million persons in camps for displaced persons in the Middle East, Germany, Austria and Italy. It recruited from thirty-five countries a staff totaling nearly 1,200 doctors, nurses, sanitary engineers, epidemiologists, nutritionists and experts in medical supplies and hospital equipment. Dr. Wilbur A. Sawyer, New York City, has served as director of UNRRA's Health Division. Several phases of the Health Division have been transferred to the Interim Commission of the World Health Organization. UNRRA has authorized the transfer of one and one-half million dollars to the commission pending the full establishment of the World Health Organization.

Annual Report of Commonwealth Fund.—The fellowships sponsored for many years by the Commonwealth Fund and suspended in 1941 were recently reestablished, and twenty British students have arrived in the United States to study under the scholarships at various universities. From 1925 to 1941, as guests of the fund for advanced study, 411 fellows visited this country. The fund continued its support of health activities and in the year ended Sept. 30, 1946 appropriated $581,567 to the Division of Rural Hospitals, $278,194 to the Division of Public Health, $294,040 to the Division of Mental Health, $224,850 for Medical Education, and $447,391 for Medical Research. The 28th annual report states that nothing during the year was more rewarding than the fund's collaboration with several young psychiatrists in the pilot course in psychotherapy for general physicians offered at the University of Minnesota last April. This course spearheaded the fund's mental hygiene program and also an attempt on a small scale to get the most pertinent parts of basic psychiatric thinking into general medicine.

Society News.—The Chapter Magnum of the International and Spanish Speaking Association of Physicians celebrated the twentieth annual meeting at the Waldorf-Astoria Hotel, New York City, on January 27 with a symposium on "The Contemporary Attitude Toward Cancer."——The seventy-fourth meeting of the National Conference of Social Work will be held in San Francisco, April 3-19, the Civic Auditorium serving as headquarters for the conference.——The Society of University Surgeons met February 13-15 as guests of the Massachusetts General, Peter Bent Brigham and Children's hospitals, Boston. The following officers were elected: Drs. Cobb Pilcher, Nashville, Tenn., president; Robert M. Zollinger, Boston, president-elect; Samuel W. Moore, New York City, secretary, and Jean M. Stevenson, Cincinnati, treasurer.——At the regular meeting of the New England Society of Physical Medicine in Boston February 19 Wayne McFarland, Washington, D. C., consultant in physical medicine, Washington Sanatorium and Hospital, discussed "Exercises for the Medical and Surgical Bed Patient." A new film demonstrating the exercises was shown.

National Health Council Expands Program.—Bailey B. Burritt has been appointed executive director of the National Health Council. Mr. Burritt will launch a program made possible through an appropriation of $78,500 by the Rockefeller Foundation, of more active leadership among the twenty national voluntary health agencies represented on the council. The National Health Council, which began to function in 1921, comprises representatives from such major organizations as the National Tuberculosis Association, the American Cancer Society, the American Heart Association, the American Public Health Association, the American Red Cross, the National Organization for Public Health Nursing and the National Safety Council. From headquarters at 1790 Broadway, New York City, a number of services available to all health agencies are maintained. The National Health Council also cooperates with state and local groups in their efforts to improve health services. One aim of the expanded program is to make a qualified field service available to states and cities where the problem of coordination among voluntary health agencies is urgent. It is also planned to expand health education services available to member agencies of the council.

General Cumming Retires as Director of Pan American Sanitary Bureau.—At the twelfth Pan American Sanitary Conference in Caracas, Venezuela, January 12-24, Gen. Hugh S. Cumming (retired), Washington, D. C., U. S. Public Health Service, was elected director emeritus of the Pan American Sanitary Bureau after twenty-six years of active service as director without remuneration. General Cumming retired as director of the bureau on January 21 and Dr. Fred L. Soper of the Rockefeller Foundation, New York, assumed the office. General Cumming was surgeon general of the U. S. Public Health Service from Jan. 27, 1920 until he retired in 1936. He was also vice president of the health section of the League of Nations, representative of the United States at the Cannes Conference and president of the Office International d'Hygiène Publique. He also served as president of the Allied Medical Mission to Poland. Dr. Soper, who has been a member of the staff of the International Health Board (now the International Health Division) of the Rockefeller Foundation since 1920, was made regional director in 1927 and associate director in 1945. In 1942 he was made consultant to the Secretary of War and served with the Allied Military Government. He has been awarded the Typhus Commission Medal.

International Society of Surgeons.—The twelfth congress of the International Society of Surgeons will be held in London, September 14-20, with Dr. Leopold Mayer, Brussels, for nearly thirty years secretary general, as president. The following subjects will be discussed: (1) "Operative Treatment of Fractures," by Professor R. Danis, Brussels; (2) "The Role of Penicillin in Surgical Practice,"Sir Alexander Fleming, London; (3) "Advances in Arteriography and Venography," Professor Reinaldo dos Santos, Lisbon; (4) "Advances in Vascular Surgery," Professor René Leriche, Paris; (5) "Surgical Treatment of Pulmonary Stenosis," Dr. Alfred Blalock, Baltimore; (6) "Role of Vasodilatation in Arterial Diseases," Dr. Julius Diez, Buenos Aires; (7) "Results of Heparin in Surgery," Dr. Clarence M. L. Crafoord, Stockholm; (8) "Skin Defects: Their Repair by Flaps and Free Skin Grafts," Professor T. Pomfret Kilner, Oxford; (9) "Results of Early Operation in War Wounds of the Lungs," Dr. Manuel Bastos-Ansart, Barcelona, and (10) "Recent Progress in the Treatment of Burns," by a Russian surgeon. Detailed summaries of the papers carefully translated into all the official languages of the conference will be circulated for discussion to follow delivery of the papers. This is the first postwar congress of the society, and those attending are asked to make early reservations with Dr. L. Dejardin, General Secretary, 141 rue Belliard, Brussels.

Shortage of Trained Medical Record Librarians.—With a grant of $22,000 from the National Foundation of Infantile Paralysis, the Educational Board of the American Association of Medical Record Librarians has designed an extension course on a nationwide basis to give inservice instruction in the field in order to meet the shortage of trained medical record librarians. Any one employed in hospital or clinical records and administrators interested in a better understanding of the record department are eligible to attend. Those previously so employed who desire to take a refresher course will be accepted. The class meets for five consecutive days to study terminology, medical ethics, related subjects, and how to use the standard nomenclature of disease and of operations. Twelve courses have been held in areas along the Eastern Coast, and further meetings are scheduled for San Francisco, March 3-7; Portland, Ore., March 10-14; Seattle, March 17-21; Omaha, March 24-28; Birmingham, Ala., April 14-18; Indianapolis, April 28-May 2; Detroit, May 12-16; Cleveland, May 19-23; Minneapolis, May 26-30, and Boston, June 9-13. More than 400 persons have been trained in inservice courses to date. The field instructor is Miss Margaret C. Taylor, Director, School for Medical Record Librarians, Rochester General Hospital, Rochester, N. Y. The National Foundation of Infantile Paralysis also has given $61,000 for scholarships to train new personnel for medical record librarians.

LATIN AMERICA

Inter-American Congress of Cardiology.—The second Inter-American Congress of Cardiology convened in Mexico City on Oct. 6, 1946 under the direction of its president, Professor Ignacio Chavez, director of the National Institute of Cardiology of Mexico. The sponsoring societies and institutions were the Sociedad Interamericana de Cardiologia, the American Heart Association, Sociedad Argentina de Cardiologia, Sociedade Bradileira de Cardiologia, Sociedad Cubana de Cardiologia, Instituto Nacional de Cardiologia de Mexico, Secretaria de Salubridad y Asistancia Publica de Mexico, Secretaria de Relaciones Exteriores de Mexico and Universidad Nacional Autonoma de Mexico. At the business meeting a permanent Inter-American Society of Cardiology was formed and a constitution adopted. Dr. Ignacio Chavez was elected honorary president for life and the National Institute of Cardiology of Mexico designated the permanent secretariat. This society is to be under a council of directors, of which five represent South and Central America and five North America. The directors from the South are Drs. Ramon Aixala Alvarez, Cuba; Herman Alessandri, Chile; Eduardo Braun Menéndez, Argentina; Teofilo Ortiz Ramirez, Mexico, and Jairo Ramos, Brazil. Those from the North are Drs. Arlie R. Barnes, Rochester, Minn.; George R. Herrmann, Galveston, Texas; William J. Kerr, San Francisco; Howard B. Sprague, Boston, and John Hepburn, Toronto, Ont. The society plans to meet every two years, the next time in 1948 in the United States. At the time of organization of the society an international council was appointed to arrange an international congress every six years.

Marriages

George Wingate Waring Jr., Boston, to Miss Louise Sawyer of Cambridge, Mass., in Gorham, Maine, December 7.

Schubert Bryan Simmons, Bay Springs, Miss., to Miss Mary Hall of Oakland in Memphis, Tenn., October 1.

Frederick Victor Vance Jr., Bristol, Tenn., to Miss Ann Lyttleton Waddell at Charlottesville, Va., October 5.

Clayton L. Rice, Logansport, Ind., to Miss Jane Austermiller of Indianapolis in Louisville, Ky., June 21.

Philip Gordon Robson, Campbell, Calif., to Miss Margaret Delphine Casey of Oshkosh, Wis., in September.

Kenneth Brenner Wright, Rocky Mount, N. C., to Miss Dorothy Ellis of Monticello, Ga., in October.

Forrest Veil Schumacher, Philadelphia, to Miss Marjorie Lillian Brown of Bryn Mawr, Pa., June 22.

Robert Lyman Paver, Belleville, N. Y., to Miss Kathleen Connelly of Darlington, Wis., September 28.

Michael Andrew Salomone, New York, to Miss Ann Louise Pizzuto of Verona, N. J., June 17.

James Walter Polk, Troy, Tenn., to Miss Hazel Killingsworth of Fort Gaines, Ga., October 6.

Mason Romaine to Mrs. Robert Randolph Parker, both of Petersburg, Va., September 7.

Deaths

Justin Allis Garvin ⊕ Cleveland; born in Valparaiso, Chile, South America, June 7, 1886; Western Reserve University School of Medicine, Cleveland, 1914; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; member, formerly secretary and chairman of the pediatric section of the Academy of Medicine of Cleveland, serving as its secretary from 1935 to 1937; served as secretary of the Cleveland Medical Library; served during World War I; formerly associate editor of the *Bulletin of the Academy of Medicine of Cleveland;* head of the medical department of the board of education of Shaker Heights; associate physician at the St. Luke's Hospital, where he died Dec. 7, 1946, aged 60, of coronary thrombosis.

Will Melville Garton ⊕ Medical Director, Rear Admiral, U. S. Navy, retired, Los Angeles; born in Des Moines, Oct. 31, 1875; State University of Iowa College of Homeopathic Medicine, Iowa City, 1896; fellow of the American College of Surgeons; entered the U. S. Navy in 1898; veteran of the Spanish-American War; served as medical aid in the eleventh naval district in San Diego; formerly inspector of medical department activities on the Atlantic Coast and also on the Pacific Coast; retired Nov. 1, 1939 on attaining the statutory retirement age; died in the Naval Hospital, Long Beach, June 7, 1946, aged 70, of perforated duodenal ulcer.

Charles Hubart Lovewell ⊕ Major, U. S. Army, retired, Spokane, Wash.; born in Coldwater, Mich., Jan. 18, 1872; Northwestern University Medical School, Chicago, 1898; served during World War I; entered the medical corps of the U. S. Army as major in 1920; later served at various stations in the United States and in the Philippines; retired Dec. 31, 1935 for disability in line of duty; formerly associated with the University of Washington in Seattle, where during World War II he served with the health center; died in the Sacred Heart Hospital Oct. 31, 1946, aged 74.

Harry Selby Purnell ⊕ Colonel, U. S. Army, retired, Berlin, Md.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; fellow of the American College of Surgeons; Army Medical School in 1903 and the Medical Field Service School Advanced Course in 1928; entered the U. S. Army in 1902; resigned in 1915 with the rank of captain; reentered the service in 1916; served during World War I; promoted through the various ranks to that of colonel in 1929; retired June 30, 1934 for disability in line of duty; died Dec. 20, 1946, aged 67, carcinoma.

Philip Abrahamson, Philadelphia; Jefferson Medical College of Philadelphia, 1899; served on the staffs of the Mount Sinai and Jefferson Medical College hospitals; died Nov. 9, 1946, aged 69.

Irving Cyrus Allen, Brooklyn; University of the City of New York Medical Department, New York, 1895; member of the American Medical Association; for many years connected with the board of education; died Dec. 3, 1946, aged 74, of coronary thrombosis.

Arthur Anderson, Guthrie, Okla.; University of Louisville (Ky.) School of Medicine, 1911; died in the Masonic Home for Aged Nov. 24, 1946, aged 64, of pneumonia and Parkinson's disease.

Albert Francis Barry, Amityville, N. Y.; University of the City of New York Medical Department, 1888; died Dec. 14, 1946, aged 79.

George W. Beery, Lancaster, Ohio; Eclectic Medical Institute, Cincinnati, 1894; member of the American Medical Association; died Dec. 23, 1946, aged 89, of cerebral hemorrhage.

Sarah Jane Boland-Wegmann, Hastings, Neb.; Kansas City (Mo.) Hahnemann Medical College, 1902; died Dec. 29, 1946, aged 66, of bilateral pyelonephritis.

Charles Hugh Breuer, San Jose, Calif.; John A. Creighton Medical College, Omaha, 1896; member of the American Medical Association; died Dec. 18, 1946, aged 80, of bronchopneumonia and cardiovascular disease.

David Z. Coats, Magee, Miss.; Louisiana State University School of Medicine, New Orleans, 1941; member of the American Medical Association; interned at the Shreveport Charity Hospital in Shreveport, La.; served a residency at the E. A. Conway Memorial Hospital in Monroe, La.; affiliated with the Magee General Hospital; killed Dec. 30, 1946, aged 30, when his pistol was accidentally discharged.

Charles C. Conlee ⊕ Cook, Neb.; Chicago College of Medicine and Surgery, 1915; served on the city board of health, as president of the Johnson County Medical Society and the board of education and as chairman of the Red Cross; died Dec. 27, 1946, aged 62, of coronary thrombosis.

Perry Wessel Cornue ⊕ Yakima, Wash.; Chicago Homeopathic Medical College, 1894; died Dec. 5, 1946, aged 75, of coronary occlusion.

George Minton Crawford, Arcadia, Calif.; Baltimore Medical College, 1892; died Nov. 7, 1946, aged 84.

Porter James Crawford ⊕ Havana, Cuba; Western Reserve University School of Medicine, Cleveland, 1920; an Associate Fellow of the American Medical Association; at one time health officer of Troy, Ohio, where he had been health officer of Miami County; Caribbean regional director, International Health Division of the Rockefeller Foundation; died Dec. 27, 1946, aged 51, of coronary thrombosis.

Charles Percy Crudup, Nebraska City, Neb.; John A. Creighton Medical College, Omaha, 1898; served as president of the chamber of commerce; died in Wake Forest, N. C., Nov. 25, 1946, aged 74.

Samuel Walton Day, Auburn, N. Y.; Syracuse University College of Medicine, 1905; on the staff of the City Hospital; died Dec. 14, 1946, aged 71, of coronary thrombosis.

Ray Russell Dearborn ⊕ Madera, Calif.; University of Vermont College of Medicine, Burlington, 1911; past president of the Fresno County Medical Society; fellow of the American College of Surgeons; owner of the Dearborn Hospital; died Dec. 29, 1946, aged 58, of coronary occlusion.

James Henry Deyerle ⊕ Harrisonburg, Va.; University College of Medicine, Richmond, 1901; served as health officer and physician at Madison College; on the staff of the Rockingham Memorial Hospital; died Nov. 26, 1946, aged 70, of coronary occlusion.

Arthur Royal Dildine, Cheney, Kan.; University of Kansas School of Medicine, Kansas City, 1906; member of the American Medical Association; also a dentist; died in the Wesley Hospital, Wichita, Dec. 26, 1946, aged 69, of coronary occlusion.

Hiram Clifford Elliott, Worcester, Mass.; Bellevue Hospital Medical College, New York, 1888; member of the American Medical Association and the Medical Society of the State of New York; at one time affiliated with the Kings County Hospital in Brooklyn; died Dec. 18, 1946, aged 89.

Arthur O. Etienne, Berwyn, Md.; Baltimore Medical College, 1896; member of the American Medical Association; served as a draft examiner for Prince Georges County at Upper Marlboro during World War I and as a member of the Maryland Draft Appeal Board during World War II, serving Baltimore and Prince Georges County among other areas; on the staff of Prince George's Hospital in Cheverly; died Dec. 14, 1946, aged 76, of coronary thrombosis.

Thomas R. Finley, Madisonville, Ky.; Missouri Medical College, St. Louis, 1877; died in the Hopkins County Hospital Dec. 26, 1946, aged 96, of a hip fracture received in a fall.

Oscar Edward Fischer, Detroit; Harvard Medical School, Boston, 1898; died Dec. 27, 1946, aged 73, of cerebral hemorrhage.

Adolph J. Foerter ⊕ Peoria, Ill.; Bennett Medical College, Chicago, 1901; on the associate medical staff of the Methodist Hospital, where he served as president of the staff and where he died Dec. 17, 1946, aged 71, of cerebral thrombosis.

George McClellan Freeman, Shoals, Ind.; Kentucky School of Medicine, Louisville, 1890; served as secretary of the Daviess-Martin Counties Medical Society, secretary of the school board and the board of health, county coroner, a member of the first pension board in Martin County and medical examiner for the draft boards during World wars I and II; died in the Daviess County Hospital in Washington, Dec. 20, 1946, aged 79.

Ambrose William Gallagher, Hamlet, N. C.; Fordham University School of Medicine, New York, 1920; member of the American Medical Association and the Medical Society of the State of New York; died Dec. 24, 1946, aged 50, of heart disease.

James Griffin Gallagher, Chicago; Loyola University School of Medicine, Chicago, 1932; member of the American Medical Association; died in the Holy Cross Hospital Dec. 22, 1946, aged 40.

Frank Williams Gardner, Columbus, Ohio; Starling Medical College, Columbus, 1907; died Dec. 1, 1946, aged 71.

Charles George Geiger, St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1888; Jefferson Medical College, Philadelphia, 1889; member of the American Medical Association; at one time on the faculty of the Ensworth Medical College; died Dec. 10, 1946, aged 81, of coronary thrombosis.

Robert Gewanter ⊕ Long Island City, N. Y.; University and Bellevue Hospital Medical College, New York, 1926; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; on the staffs of the Greenpoint Hospital in Brooklyn and the Gouverneur and Bellevue hospitals in New York; died Nov. 10, 1946, aged 44, of heart disease.

Augustus George Gigger, Falmouth, Mass.; Boston University School of Medicine, 1906; member of the American Medical Association; died in Barnstable Nov. 27, 1946, aged 68, of bronchopneumonia.

George Yancey Gillespie Sr., Duck Hill, Miss.; Memphis (Tenn.) Hospital Medical College, 1883; died in Greenwood Dec. 24, 1946, aged 91.

Edwin Blanchard Glass, Los Angeles; Baylor University College of Medicine, Dallas, Texas, 1928; interned at St. Vincent's Hospital; found dead Dec. 6, 1946, aged 42.

Harman Reasoner Goldthwaite ⊕ Marion, Ind.; Temple University School of Medicine, Philadelphia, 1922; past president and secretary of the Grant County Medical Society; served as school physician; on the staff of the Marion General Hospital; died Dec. 8, 1946, aged 53, of coronary thrombosis.

George Augustus Gregory ⊕ Boothbay Harbor, Maine; Medical School of Maine, Portland, 1891; honorary member of the Maine Medical Association; formerly associated with the U. S. Public Health Service; served on the staff of St. Andrews Hospital; died Dec. 1, 1946, aged 81, of chronic nephritis.

Willard Arthur Guyton Jr., East St. Louis, Ill.; University of Illinois College of Medicine, Chicago, 1943; interned at St. Louis City Hospital; diplomate of the National Board of Medical Examiners; began active duty as a first lieutenant in the medical corps, Army of the United States, in January 1944; promoted to captain; released from active duty in August 1946; died in St. Mary's Hospital Dec. 9, 1946, aged 26, of sarcoma.

Bishop Adams Hall, Forest Hills, N. Y.; Kentucky School of Medicine, Louisville, 1890; died Dec. 9, 1946, aged 89.

Ralph William Hall, Dover, N. H.; Long Island College Hospital, Brooklyn, 1911; died in Concord Sept. 7, 1946, aged 63.

Nicholas N. Harin, New York; Beogradskog Universiteta Medecinski Fakultet, Beograd (Belgrade) Yugoslavia, 1930; interned at the Hudson River Hospital in Poughkeepsie, N. Y.; served a residency at the Pilgrim State Hospital in Brentwood, N. Y.; resident physician at the New York City Farm Colony in Staten Island, where he died Nov. 18, 1946, aged 46.

Charles Hickman Harris, New Paris, Ohio; Starling Medical College, Columbus, 1890; Jefferson Medical College of Philadelphia, 1891; member of the American Medical Association; served during World War I; also a druggist; died recently, aged 79.

William John Harris, Valley Park, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1875; served on the staff of the Christian Hospital in St. Louis; died Dec. 25, 1946, aged 94.

James Henry Hartman ⊕ Jacksonville, Fla.; College of Physicians and Surgeons, Baltimore, 1904; member of the Southeastern Surgical Congress and the Southern Medical Association; on the staff of St. Vincent's Hospital; died Dec. 26, 1946, aged 66, of coronary occlusion.

George Richard Hays, Marissa, Ill.; Beaumont Hospital Medical College, St. Louis, 1896; member of the American Medical Association; affiliated with St. Elizabeth's Hospital in Belleville; died Dec. 7, 1946, aged 75, of heart disease.

William Harrison Hemker ⊕ Pacific, Mo.; St. Louis University School of Medicine, 1904; died Oct. 6, 1946, aged 65, of angina pectoris.

Arthur John Herrmann, Los Angeles; Rush Medical College, Chicago, 1888; affiliated with Hospital of the Good Samaritan and the California Lutheran Hospital, where he died Dec. 25, 1946, aged 81, of carcinoma of the colon.

Henry George Hertel, Giddings, Texas; Washington University School of Medicine, St. Louis, 1901; county health officer; past president of the chamber of commerce; died in St. Francis Hospital, Brenham, Dec. 6, 1946, aged 72, of coronary occlusion.

Julian Adolph Hielscher, Mankato, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1891; vice president of the American State Bank of Mankato; served during World War I, as health officer of Mankato, on the library board and school board; died Oct. 9, 1946, aged 82.

Eleanor Jane Hill, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; member of the American Medical Association; formerly school physician; on the staffs of the Asbury and Northwestern hospitals; died Dec. 12, 1946, aged 78, of Parkinson's disease and chronic arthritis.

Harold Phillips Hill ⊕ San Francisco; Medical Department of the University of California, San Francisco, 1901; clinical professor of medicine emeritus at the Stanford University School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; on the staff of St. Luke's Hospital; consultant in medicine, San Francisco Hospital; died Dec. 3, 1946, aged 69, of metastatic epithelioma.

Samuel Hirshfeld ⊕ Los Angeles; Columbia University College of Physicians and Surgeons, New York, 1918; fellow of the American College of Surgeons; on the staffs of the Hospital of the Good Samaritan and Cedars of Lebanon Hospital; died Dec. 13, 1946, aged 51.

William Milo Hogle ⊕ Keokuk, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1901; served as president of the Lee County Medical Society; on the staffs of the Graham Protestant and St. Joseph's hospitals; died Dec. 29, 1946, aged 72, of heart disease.

Lewis Holladay, Orange, Va.; University of Virginia Department of Medicine, Charlottesville, 1896; member of the American Medical Association; served as a member of the examining boards of World wars I and II, member of the state board of medical examiners, as county coroner, as county health officer and as local surgeon for Chesapeake and Ohio Railroad; member of the board of directors of the National Bank of Orange; died Dec. 10, 1946, aged 77, of coronary thrombosis.

Alonzo Huffman, Russell, Ky.; Medical College of Virginia, Richmond, 1928; member of the American Medical Association; served overseas during World War I; organized the county health department and served as a member of the county board of health; past president of the Rotary Club; physician for the Chesapeake and Ohio Railway; on the staff of the Lawrence County General Hospital in Ironton, Ohio, where he died Dec. 24, 1946, aged 50, of heart disease.

Edgar Hamill Hughes, Brooklyn; Fordham University School of Medicine, New York, 1914; specialist certified by the American Board of Otolaryngology; served on the staffs of St. Mary's, St. Peter's and Brooklyn hospitals; died Dec. 27, 1946, aged 55, of coronary thrombosis.

Mary Elizabeth Hyatt-Smith, Indianapolis; Louisville National Medical College, Medical Department State University, 1909; died Dec. 3, 1946, aged 72, of cardiovascular renal disease.

Nouri Iskandar Ishkhanian ⊕ West New York, N. J.; American University of Beirut School of Medicine, Syria, 1912; on the staff of the North Hudson Hospital in Weehawken; died in the Christ Hospital in Jersey City Dec. 30, 1946, aged 58, of retroperitoneal lymphosarcoma.

Franklin Taylor Kilgore, Yorktown, Ind.; Medical College of Indiana, Indianapolis, 1898; member of the American Medical Association; served overseas during World War I; major, medical reserve corps, not on active duty; formerly county coroner; on the staff of the Ball Memorial Hospital, Muncie, where he died Dec. 22, 1946, aged 70, of arteriosclerotic cardiovascular disease.

Thomas W. Koon, Cumberland, Md.; College of Physicians and Surgeons, Baltimore, 1893; member of the American Medical Association; formerly mayor of Cumberland; member of the state industrial accident commission; on the staff of the Allegany Hospital; died Dec. 5, 1946, aged 76.

James Franklin Lane, Dulce, N. M.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1910; member of the American Medical Association; special physician at large, Indian Service; served during World War I; died in the Indian Hospital, Santa Fe, Nov. 12, 1946, aged 63.

Joseph Leon Lane ⊕ Seattle; Sioux City (Iowa) College of Medicine, 1903; found dead Dec. 24, 1946, aged 68.

Wilson Terah Lawson, Danville, Ind.; Miami Medical College, Cincinnati, 1878; member of the American Medical Association; for many years secretary and at one time president of the Hendricks County Medical Society; county health officer; formerly county coroner; served as trustee of the Central Normal College; died in the Methodist Hospital, Indianapolis, Dec. 14, 1946, aged 97, of uremia and prostatism.

Walter Sidders Lay ⊕ Hamden, Conn.; Yale University School of Medicine, New Haven, 1901; served during World

War I; colonel, medical reserve corps, U. S. Army, not on active duty; formerly health officer of Hamden; died Dec. 10, 1946, aged 76.

Thomas Everett Leslie, Olive Hill, Ky.; University of Arkansas School of Medicine, Little Rock, 1918; served during World War I; died Dec. 25, 1946, aged 57, of heart disease.

George Griffin Lewis, New York; Albany (N. Y.) Medical College, 1890; member of the American Medical Association; fellow of the American College of Surgeons; on the staff of the Crouse-Irving Hospital; died in December, aged 80, of coronary thrombosis.

Mortimer Lippmann ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1920; affiliated with the Crown Heights Hospital; died Dec. 10, 1946, aged 53, of coronary disease.

Perlee W. McCarty, Indianapolis; Medical College of Indiana, Indianapolis, 1904; died Dec. 23, 1946, aged 76, of bronchopneumonia and cardiovascular renal disease.

Bernard Anthony McDermott, Washington, D. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; affiliated with the Veterans Administration; served in the regular army and during World War I; major, medical reserve corps, U. S. Army, not on active duty; died Dec. 24, 1946, aged 62.

Norman Percy McGay ⊕ Cleveland; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; died in the Woman's Hospital Dec. 11, 1946, aged 67, of heart disease.

Robert Armand Watters McKeldin, Philadelphia; National University Medical Department, Washington, D. C., 1902; formerly medical supervisor for the board of education; major, medical reserve corps, U. S. Army, not on active duty; died Dec. 10, 1946, aged 71, of cerebral thrombosis.

Alfred Willits McKinley, Drexel Hill, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1937; member of the American Medical Association; served on the staffs of the Fitzgerald-Mercy Hospital in Darby, Delaware County Hospital, Presbyterian Hospital in Philadelphia and the Philadelphia General Hospital, where he died Dec. 6, 1946, aged 36, of pelvic abscess, generalized peritonitis and pulmonary tuberculosis.

Charles Leroy McKittrick, Los Angeles; Kansas City (Mo.) Medical College, 1904; died in the California Hospital Dec. 30, 1946, aged 68, of acute coronary thrombosis.

Clarence Alfred MacMinn, Round Lake, N. Y.; Bellevue Hospital Medical College, New York, 1898; member of the American Medical Association; health officer and school physician; for many years on the staff of the Ellis Hospital in Schenectady; on the staff of the Saratoga Hospital, Saratoga Springs, where he died Dec. 11, 1946, aged 74, of hemorrhage from peptic ulcer.

John Joseph McNamara ⊕ Lowell, Mass.; Tufts College Medical School, Boston, 1923; died Nov. 13, 1946, aged 51, of coronary occlusion.

Frank Fremont Marshall ⊕ L'Anse, Mich.; Harvard Medical School, Boston, 1911; served in France during World War I; president of the township school board; physician designate for the Indian Service, U. S. Department of Interior; at one time physician for the Ford Motor Company; on the staff of St. Joseph's Hospital in Hancock; died in St. Mary's Hospital, Marquette, Dec. 16, 1946, aged 66, of coronary thrombosis.

Francis V. Martin ⊕ Michigan City, Ind.; University of Michigan Homeopathic Medical School, Ann Arbor, 1892; member of the Radiological Society of North America, Inc.; part owner of the Clinic Hospital, where he died Dec. 13, 1946, aged 80, of coronary occlusion.

Thomas Joseph Moran, Alton, Ill.; Chicago Medical School, 1931; member of the American Medical Association; affiliated with St. Joseph's Hospital and Alton Memorial Hospital, where he died Dec. 14, 1946, aged 48, of cerebral hemorrhage.

James Kane Mullen, Pocatello, Idaho; George Washington University School of Medicine, Washington, D. C., 1944; interned at St. Mary's Hospital in San Francisco; served in the medical corps of the U. S. Naval Reserve during World War II; recently received an appointment to the faculty of the University of Colorado School of Medicine and a residency in radiology at the Colorado General Hospital in the city of Denver, where he was shot and killed in a hotel Oct. 1, 1946, aged 26, when struck by a stray bullet.

Charles Augustus O'Quinn, Perry, Fla.; University of Georgia Medical Department, Augusta, 1901; member of the American Medical Association; served as health officer of Madison and Taylor counties; died in Thomasville, Ga., Dec. 9, 1946, aged 75.

Chester Moore Peters ⊕ Canton, Ohio; the Hahnemann Medical College and Hospital, Chicago, 1915; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; served during World War I; colonel, medical reserve corps, not on active duty; formerly health officer of Stark County; for many years on the staff of the Mercy Hospital; died Dec. 7, 1946, aged 65, of cerebral hemorrhage.

Ralph Edgar Pray, Salinas, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1925; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics and the American Medical Association; began active duty as a major in the medical corps, Army of the United States, in September 1942; served in France and England; service terminated with rank of lieutenant colonel in January 1946; died in San Francisco Dec. 18, 1946, aged 49, of brain tumor.

Robert Black Price ⊕ Jackson, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1906; served as a missionary in China; died Dec. 10, 1946, aged 65.

Carl Christian Rasmussen, Des Moines; Northwestern University Medical School, Chicago, 1925; member of the American Medical Association; formerly a member of the school board in Ashland, Ill.; died in the Winecoff Hotel fire in Atlanta, Ga., Dec. 7, 1946, aged 49.

May Turner Riach ⊕ San Diego, Calif.; George Washington University School of Medicine, Washington, D. C., 1913; died Dec. 7, 1946, aged 56.

Aaron Rokeach, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1903; died Dec. 6, 1946, aged 70, of cerebral hemorrhage.

Charles Clifford Ross, Hookstown, Pa.; Medical Department of the Western University of Pennsylvania, Pittsburgh, 1907; died Sept. 18, 1946, aged 70, of diabetes mellitus.

Stancill W. Rushing, Detroit; Meharry Medical College, Nashville, 1915; died in the Edyth K. Thomas Memorial Hospital Dec. 22, 1946, aged 63.

Herman Scaison, Mount Vernon, N. Y.; Eclectic Medical College of the City of New York, New York, 1898; served during World War I; medical examiner for Selective Service Board number 101 of New York during World War II; on the staff of the Mount Vernon Hospital, where he died Dec. 12, 1946, aged 70, of infectious hepatitis.

Joseph Semerak ⊕ Oak Park, Ill.; Reliance Medical College, Chicago, 1909; died Dec. 17, 1946, aged 80, of carcinoma.

Thomas Laidlaw Shearer, Baltimore; University of Edinburgh Faculty of Medicine, Scotland, 1882; fellow of the American College of Physicians; acting medical examining officer at Baltimore of recruits for the British and Canadian armies; died Dec. 13, 1946, aged 87, of arteriosclerosis.

Lloyd Otterbein Sholty, LaFayette, Ind.; Indiana University School of Medicine, Indianapolis, 1912; member of the American Medical Association; served during World War I; on the staffs of St. Elizabeth and LaFayette Home hospitals; died Dec. 24, 1946, aged 62, of coronary occlusion.

Howard Hazlett Smith, Rocky River, Ohio; Western Reserve University Medical Department, Cleveland, 1912; member of the American Medical Association; affiliated with the Lakewood (Ohio) Hospital; died Dec. 23, 1946, aged 60, of cerebral hemorrhage.

Michael Smith ⊕ West Palm Beach, Fla.; University and Bellevue Hospital Medical College, New York, 1932; interned at the Nathan and Miriam Barnert Memorial Hospital in Paterson, N. J.; awarded the Bronze Star Medal for service during World War II; began active duty as a captain in the Medical Corps, Army of the United States, on Dec. 28, 1942 and was released in November 1945 with the rank of major; died Dec. 5, 1946, aged 38, of coronary thrombosis.

Benjamin Charles Tarnutzer ⊕ Los Angeles; Western Reserve University Medical Department, Cleveland, 1902; served on the staff of the California Hospital; died Nov. 11, 1946, aged 68, of heart disease.

Frederick Glenn Templeton, West Frankfort, Ill.; Loyola University School of Medicine, Chicago, 1934; interned at the Cook County Hospital in Chicago and St. Catherine's Hospital in East Chicago, Ind.; served during World War II; drowned Nov. 26, 1946, aged 37, when a motorboat sank on a lake when he was duck hunting.

Foreign Letters

LONDON

The Conflict on the National Health Service Act

As reported in a previous letter, the presidents of the three Colleges—of Physicians, of Surgeons and of Obstetrics and Gynecology—intervened in the conflict between the British Medical Association and the minister of health, Mr. Bevan, by sending a joint letter. To this the minister made a conciliatory reply. As a result the council of the British Medical Association held a special meeting and revoked its previous recommendation to the representative body of the association to refuse to negotiate with him. According to the official report the council carefully examined the situation created by Mr. Bevan's letter as regards both its tone and its substance. The chairman of the council strongly contested the minister's statement that he had been willing to negotiate with the profession. It was evident that the minister had taken serious note of the position following the plebiscite and the council's recommendation. The following important resolution was passed by the council without any dissent: "That the association, having considered the final results of the plebiscite and the minister's letter of January 6 to the presidents of the Royal Colleges, and desiring to secure for the people the best possible health service, is willing that discussions be entered into with the minister to that end, provided such discussions are comprehensive in their scope and that the possibility that they may lead to further legislation is not excluded; that after the conclusion of these discussions a second plebiscite of the profession be taken on the issue of entering the service." So it looks as if, after all, the conflict between the profession and the government as to a national health service will be settled in the characteristically English way of compromise.

A Food Delivery Scheme for the Aged to Diminish the Overcrowding of Hospitals

At a conference on special modes of catering for the aged, invalids and infirm, organized by the London Council of Social Service, it was pointed out that the present overcrowding of hospitals could be relieved by a well organized catering service delivering meals to invalids in their own homes. Dr. F. Avery Jones of the Central Middlesex Hospital said that at least 10 to 15 per cent of patients were admitted to the hospital not for any specific treatment but because they needed food, rest and medical supervision which should be provided at home. A food delivery service which served midday meals to the sick and infirm would bridge the difficult gap when the working members of the family were absent, and thus provide an alternative to hospital admission. The scheme was feasible, and was already being carried out on a small scale by the Invalid Kitchens of London. He also suggested another way in which a catering service could reduce hospital admissions. Old people living alone did not always eat enough. They lost energy and had less inclination to queue for food at the shops (a practice due to the shortage of food and rationing of the war which still continues). Their resistance to illness was diminished and they eventually came to the hospital with maladies such as anemia and bronchitis. If doctors could arrange for them to eat at special centers, this would be better medicine than a white bottle of placebo.

Dr. Magnus Pyke, principal scientific officer to the Ministry of Food, said there were many serious gaps in the scientific knowledge of the physiologic requirements of the aged. The London Council of Social Service would make a valuable contribution to the problem if it could bring together scientific workers and the aged people whose needs were so urgently calling for study. The chairman of the Middlesex Public Health Committee said that old people should receive the same kind of assistance that was afforded to the blind.

The Extermination of "Phossy Jaw"

The death at the age of 70 of Sir Alexander Maguire, match manufacturer, recalls the long campaign against "phossy jaw" (phosphorus necrosis) in which he played a decisive part. The ravages of this disease extended all over the world wherever matches were made. After much negotiation and some opposition Maguire got the consent of his fellow manufacturers to the necessary legislation for the white phosphorus match prohibition bill, which became law in 1908. This good example soon spread to the British dominions and to the United States. The result was the disappearance from the world of a serious disease—surely a unique event in preventive medicine.

Inoculation of Intending Travelers Against Yellow Fever

The Ministry of Health has arranged for travelers who intend to visit yellow fever areas to have free inoculation against the disease. These will be given in London at the Wellcome Foundation and at nine of the principal cities of Britain, where centers will be established for the purpose.

New Extracts of Digitalis

At the Practical Pharmacologic Laboratory of the University of Liége the problem of cardioactive heterosides of digitalis purpurea has been studied by Florent Ulrix by means of the chromatograph. This technic has permitted the total separation of the various heterosides and has made evident the nonexistence of gitalin in the examined indigenous digitalis. In addition, the presence of active heterosides, unknown and probably more complex than Purpurea glucosides A and B of Stoll, have been demonstrated. They have been designated as Purpurea glucosides A_2 and B_2 and Purpurea glucosides A_3 and B_3. The chromatographic method is simpler than the usual methods and makes it possible to obtain pure heterosides. A patent has been sought on the method.

Ovarian Hormone and Mammary Cancer

Dr. Desaive has recently published in the *Acta Chirurgica Belgica* a study of the influence of ovarian suppression on the development of mammary cancer. If the ovary exerts an influence on developing mammary cancer, this influence is probably only unfavorable; castration, preferably the roentgenologic form, must thus, at least in theory, attain the role of an accessory treatment of mammary cancer. However, in practice this method has not given sufficiently convincing proof that it deserves to be generally recommended. Consequently, endocrine studies do not justify an attempted prophylaxis of mammary cancer by this means

Silicosis

Dr. Langelez, chief of the Service of Occupational Medicine, professor at the University of Brussels and in the Institute of Higher Studies, will publish an important work on silicosis. In Belgium only since 1937 has the pathologic condition of the lung due to the inhalation of silicon dioxide been recognized as ground for legal compensation provided for occupational diseases. Synthesizing the contributions of various investigators, the work of numerous laboratories and the discussions of several conventions, Langelez contributes information that will be useful to industrial physicians and to those concerned with legal medicine.

Lead Intoxication from Bread

Before the Academy of Medicine of Belgium, Nélis and Stijns described a large number of alimentary lead intoxications in a Luxembourg community. Inquiry revealed that the source was a flour which contained lead and had been obtained from a mill the grindstone of which had been relined with lead over a total surface of 300 square centimeters. Samples of the milled flours contained between 40 and 130 mg. of lead per kilogram, and bread made with this flour contained 30 mg. per kilogram. In all those who became poisoned a fifteen day period of fatigue was followed suddenly by abdominal pains, stubborn constipation, bile stained vomit and anorexia. Loss of weight and anemia generally were severe. There was neither fever nor changes in arterial pressure. Burton's blue line on the gums was distinct in nearly all the cases. The blood contained numerous erythrocytes with basophil granulations. The urine contained lead. All patients were cured, but the majority had a prolonged convalescence. The authors noted that individual sensitivity to lead varies greatly and that children exhibited a special resistance to this form of intoxication.

Pneumonoconiosis in Cutters of Fireproof Brick

Before the Belgian Society of Occupational Medicine M. André reported the professional and pathologic history of a certain number of workers who, after working for years in a limestone quarry, later worked as cutters of fireproof bricks in glass factories and metallurgical shops. These men were completely incapacitated for work because of dyspnea, which in some cases was extreme. The inhaled dusts contain particles of silica. X-ray films reveal the development and aggravation of the disorder. In some there is true silicosis; in others a silicotuberculous syndrome exists; in still others simple fibrosis. Most striking is the absence of parallelism between the roentgenograms which generally do not show advanced development and the grave functional symptoms. The author concludes that the cutters of fireproof bricks should benefit from the advantages provided by the law on occupational diseases (pneumonoconioses).

ITALY

Hypertrophy of the Thymus

Scarzella and Benassi of the Ospedale Civile di Biella, Piemonte, are publishing through Casa Editrice Ambrosiana, Milan, an interesting work on 96 cases of infantile thymus hypertrophy. In each case the history, radiography of the thorax, treatment and an account of the course of the illness are given, with a review after several years. The symptoms of hypertrophy include a tendency to cyanosis, with a paroxysmal tendency at the slightest effort made by child (prolonged suckling, coughing), thymus asthma and finally, in serious cases, thymic death. Thymic death happens so unexpectedly that sometimes, as Curshmann of Rostock remarks, it is a convenient *diagnosis* resorted to in the case of the unexpected death of an infant, when the cause cannot be determined. Sometimes, in fact, it follows a slight fall, a slight knock or an injection of serum. The concentration of many cases in limited areas of Piemonte has suggested the opinion that thymus hypertrophy may be attributed to special feeding adopted by the mothers during pregnancy. This does not seem to be shared by the writers who invariably found the mothers feeding on diets of definite nutritive value.

STATUS THYMICOLYMPHATICUS

When thymic hypertrophy persists, particularly morbid manifestations can be traced in adolescence: hypogenitalism, putting on of fat with a rounding of the body form in males, and strong tendencies to allergic illness. Is the cause of status thymicolymphaticus (defined by Dr. Pende as a hyperthymic syndrome and as probably due to the active glutathione body of the thymic hormone) due to thymic hypertrophy (which is found in some babies still breast feeding?). The question is important because, given the simplicity of the procedure by which hypertrophy of the gland can be ascertained by x-ray and that the hypertrophy can be diminished with few applications of x-ray irradiations, the problem could be resolved by preventive treatment with radiation in early infancy. According to the writers the thymus gland is involved in the nutritive mechanism of carbohydrates. Pende, an Italian endocrinologist, claims to cure the illness, which he describes as "hyperthymic syndrome" (which is none other than an adolescent thymicolymphatic illness) by the application of x-rays. Consequently, since, both with a curtailing of the carbohydrates in the diet and with the use of x-rays in irradiation of the thymus, the thymicolymphaticus state of adolescents can be successfully modified, a relation between the two morbid conditions can hardly be denied.

THYMIC DEATH

To what is thymic death due? A simple shock can cause it. It was thought to be due to an excess of thymic hormone, which acted on the myocardial fibers. Lability of the myocardial fibers would result in a general grave form of atonia and asthenia, owing to which the slightest strain might have fatal results. Yet the writers, at necropsy, have never found signs of lesions of the myocardium. They believe that the myocardium is affected indirectly. Why in thymic hypertrophy is the heart always enlarged? The reason is that the enlarged gland presses mechanically on the large ducts at the base of the heart and causes a circulatory stasis, so that, following a regression of the hypertrophy on application of x-rays to the thymus, the heart also returns to normal size. There are, however, some cases in which the heart, though becoming normal through reduction of the size of the thymus, has shown signs of unsuspected overstrain at the onset of a successive illness. This is illustrated by a baby whose heart was weakened because of an acute infective illness, though the x-rays showed a reduction to normal after irradiation of the thymus. In an affected myocardium other factors exist apart from the existence of a simple cardiac hypertrophy. It is put forward that a cellular degeneration and lymphocytic infiltration of the myocardium also exist. At the same time the pressure on the bronchial veins and the azygos system exercised by a large thymus has repercussions also on the encephalic mass. Then follows, as the result of cerebral stasis, a disturbance of the cardiac-respiratory innervation whose center is controlled by the brain. Added to this is the compression of the pulmonary vein caused by the thymus. Thymic death, therefore, would presumably be due to a complex of factors: mechanical circulatory cardiac stasis, bronchial circulatory stasis (of the pulmonary vein) and a disturbance of the cardiac-respiratory innervation, typically characterized by the violent fatal effect of the presumable blocking of a vagal discharge.

Lack of American Medical Books in Italy

Dr. Macdonald in his communication from Australia in The Journal Dec. 21, 1946 is right in declaring that The Journal is almost universally read. In Italy it is read avidly and is looked for in the libraries of the universities which receive it. It is the one which really informs the Italian medical public about the great production of American medical literature. However much we look for American medical books here, we can find but few. They are in great demand and would sell well, particularly those on nutrition, cardiology, biochemistry, embryology, radiology and electrocardiology. An exhibition in Milan this week of 1,500 American books attracted many visitors.

Correspondence

ETHICAL RESPONSIBILITIES OF THE GERMAN MEDICAL PROFESSION

To the Editor:—Permit me to register the opinion opposite to that expressed by Dr. Enloe in The Journal, Dec. 28, 1946. Dr. Enloe thinks that it is wrong "to condemn the German medical profession as a body" for the brutalities committed by physicians in Nazi concentration camps. He gives two reasons: one, that "the German organizations" did not know; two, that they couldn't do anything about it. It is my opinion, that not only did they know enough about it, but it was their duty to know. With regard to the question of what they could have done about it, Dr. Enloe states very correctly that "One was better off not to know."

Our ethical attitude toward the German medical profession is not just a theoretical problem. It has a great deal to do with our own responsibilities. For years now, lay people and journalists from first and second hand information have been making very serious accusations concerning brutalities in American psychiatric hospitals. It is not a question in this communication of mine whether or not these allegations may be true (I, for one, believe they are); but if at a later date it should turn out that widespread brutalities do exist, that they have never been as thoroughly and skilfully investigated as they should have been and that psychiatrists in high places have never been held to account for permitting them, then it is my opinion that the whole American psychiatric profession and the foundations that have made large contributions to psychiatric institutions must bear the full responsibility. It may be true that one is "better off not to know." But that would not be an excuse; it would be an indictment.

Frederic Wertham, M.D., New York.

ASSAY OF THIAMINE

To the Editor:—In The Journal Dec. 7, 1946, under the heading "Bureau of Investigation," appears an abstract of a notice of judgment obtained by the Food and Drug Administration against the firm of Charles C. Haskell & Co., Inc., because of the shipment in interstate commerce of a preparation known as Pantabee, which was considered as misbranded because of a claimed deficiency of 25 per cent in its thiamine content. The date of this shipment as given in the abstract indicates that it occurred almost four years ago, in January 1943.

Pantabee is a powder consisting of a yeast concentrate fortified by addition of synthetic vitamins of the B complex; each capsule was stated to contain 1 mg. of thiamine hydrochloride. The lot from which the Food and Drug Administration obtained samples was prepared in April 1942 in such a manner that each capsule contained 6 grains of the yeast concentrate, containing slightly more than 0.2 mg. of thiamine hydrochloride. To this was added, per capsule, 0.8 mg. of thiamine hydrochloride, as well as stated amounts of the other B vitamins. According to the assay by the Food and Drug Administration there was present *only* 0.75 mg. of thiamine hydrochloride per capsule.

In view of the careful control exercised in the mixing of Pantabee powder, we submitted samples of this same lot for assay by three independent laboratories, to receive conflicting and confusing reports. The problem was investigated by Dr. Richard Neale, formerly of this city, and led to his conclusion that the yeast used by us interfered with the determination of thiamine by a colorimetric method he used. Subsequently Brown, Hamm and Harrison (*J. Biol. Chem.* **151**:153, 1943) carried out a careful comparison of the results of bioassay and assay by the thiochrome method for determination of thiamine and, from assay of enriched tablets from three different manufacturers, found that the thiochrome method consistently failed to indicate the true thiamine content, as indicated by the bioassay method.

We are unaware what method was used by the Food and Drug Administration in determining thiamine in our Pantabee capsules. Our request that they add thiamine hydrochloride to a sample of the yeast extract used by us and repeat their assay was refused on the ground that the agency could not carry on such "collaborative" investigations.

We felt and still feel that there is good reason to believe that the samples of Pantabee capsules tested by the Food and Drug Administration were not deficient in thiamine content but we have subsequently added an excess of 25 per cent synthetic thiamine hydrochloride in the preparation of Pantabee powder, and assays of each lot have consistently shown more than 1 mg. of thiamine hydrochloride per capsule.

Charles C. Haskell & Co., Inc.,
Charles C. Haskell, M.D., Richmond, Va.

PENICILLIN IN VINCENT'S ANGINA

To the Editor:—In the abstract of my paper on "Penicillin in the Oral Therapy of Vincent's Angina and Acute Follicular Tonsillitis" (*Arch. Otolaryng.* **44**:409 [Oct.] 1946) appearing in The Journal January 11 appears the statement "Hopp treated 25 patients who had Vincent's angina with penicillin sodium in gelatin capsules, 10,000 units each, one being given every two hours for ten doses." This wording might give the impression to the reader that capsules were to be swallowed for possible systemic effect whereas in the original work the capsules were permitted to dissolve in the buccal sulcus. Of course, this method of administration did not exclude the possibility of a systemic absorption of penicillin from the swallowing of saturated saliva as I did no penicillin blood level determinations because of the lack of the necessary facilities, overseas. However, the work was intended primarily as a test of local effect of penicillin.

Eugene S. Hopp, M.D., San Francisco.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Feb. 22, page 569.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various centers, March 17-19. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Written.* Chicago, March 17. *Oral.* Philadelphia, June 5-7. Final date for filing application is April 1. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pathology: Philadelphia, June 3-4. Final date for filing application is April 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

American Board of Pediatrics: Effective May 1, application will be $125.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Chiropractic Practice Act: Board's Right to Cancel Licenses Without Notice or Hearing—Reversal of Previous Decision.—The petitioners, about twenty-five chiropractors, filed a proceeding for a writ of mandate against the defendant, state board of chiropractic examiners, commanding the board to annul its order canceling the petitioners' licenses to practice chiropractic. From a judgment granting the writ, the board appealed to the district court of appeals, third district, California.

In July 1942 the defendant board adopted a resolution authorizing the giving of examinations for chiropractic licenses by one member of the board, the purpose being to grant emergency examinations for applicants expecting to go into the armed services and permitting them to take examinations under the authority of the board member nearest their residence. Pursuant to this resolution a number of examinations were given by the individual members of the board. The examinations were of the same type and character as those previously given by the entire board, and the questions asked were taken from those which had been approved by the board for previous examinations. In January 1943 the entire board considered all the examination papers and, by resolution, approved the special examinations and the licenses issued as a result thereof. In June 1943 an investigator of the board swore out a complaint, and an order was issued against the petitioners requiring them to show cause why their several licenses should not be revoked. A hearing was had in the matter in July, at which time the board found that "none of the matters presented was ground for revocation of the licenses, that all were issued by the Board after a resolution had been duly and regularly passed by it authorizing the giving of special examinations; that each of such examinations was given by a member of the Board from questions of the same type as used in connection with previous examinations, that each of the persons examined passed by more than a passing grade, that there had been no complaints as to their ability, knowledge or skill, that the Board had authorized special examinations in the past for special purposes, and that after the examinations were held the papers in each case, together with the results, had been forwarded to Sacramento, after which the grades were duly entered and the licenses were issued and signed by four or five members of the Board in regular sessions; that although some applicants were given numbers, nearly all examinations were given to individuals at individual times and sittings, and it would have been an idle act to designate the person by number, and that this requirement had been waived by the Board's resolution pursuant to powers given by section 4 of the Act giving the Board power to adopt rules and regulations for the performance of its work; and that the Board deemed it proper and necessary to give these special examinations in the manner given." In May 1944, by which time the personnel of the defendant board had completely changed, the board adopted a resolution canceling the license of each petitioner and directing the board investigator to obtain the certificates and to transmit them to the board. This resolution was made without notice or hearing.

The Chiropractic Law (Deering's General Laws, act 4811) provides for a board of five members. Section 4 gives the board power to adopt such rules and regulations as it may deem proper and necessary for the performance of its work, to examine applicants and to issue and revoke licenses to practice chiropractic. Section 6 provides that the board shall meet "as a board of examiners" on stated days in January and July, and at such other times and places as may be found necessary for performance of their duties, that each applicant shall be designated by a number instead of a name so that identity will not be disclosed to the examiners until the papers are graded and that all examinations shall be in writing. Section 10 provides that the board may revoke a license or may cause a licensee's name to be removed from all records of licensed practitioners of chiropractic in this state, on the following grounds: for "the employment of fraud or deception in applying for a license or in passing an examination" as provided in this act; for practicing under a false or assumed name; for the personation of another practitioner of like or a different name; for the conviction of a crime involving moral turpitude, for habitual intemperance and for advertising in a proscribed manner. Section 10 further provides that any licentiate against whom any of the foregoing grounds for revoking a license are presented to the board with a view to revoking his license shall be furnished with a copy of the complaint and shall have a hearing before the board in person or by an attorney.

The defendant contended that all of the proceedings prior to May 1944 were void, and it based such contention on the premise that, under the act, examinations for licenses must be given by the board sitting as such, that the giving of an examination by a single member is unauthorized, and that, even though such examinations may have been taken and passed by the applicants and the licenses issued thereon signed and approved by the members, nevertheless, since it does not appear that the board sitting as such prepared the question, or that the board or a majority of its members were present when the examinations were given, or that the papers presented by the examinees were graded by the board as such, and because it appears that the applicants were not designated by number but that their identity was known at the time the examinations were given, and even though the questions asked were those which had previously been prepared by the board, the examinations were passed with satisfactory grades, and the licensees were themselves without fault, nevertheless their licenses may be summarily canceled by the board, without notice or hearing.

The court pointed out that none of the cases cited by the board hold that because a statute provides, as does the one before us, that the board "shall have power: . . . (c) To examine applicants and to issue and revoke licenses to practice chiropractic, as herein provided," it necessarily follows that each and every step taken in the giving of examinations must be made by the board at a regularly convened meeting. Though this act does not provide for the giving of examinations by individual members, it does not expressly prohibit such action if authorized by the board at a regularly convened meeting. Even assuming that such action was authorized, the court continued, the question to be decided is whether the board had the power, without notice, and without further charges or evidence, to reverse its previous action and cancel the licenses in May 1944, after having issued and signed the licenses in due form and approved their issuance by a resolution adopted in January 1943, and having further found, after a full hearing in July 1943, that there were no grounds for canceling said licenses. We are of the opinion, said the court, that the board was without power. It must be conceded that no such power was granted by the act itself and that section 10, providing for the revocation of licenses by the board, specifies the grounds of such revocation and requires notice and a hearing on such charges as constitute grounds for revocation. Where a board has once acted on a motion it has exhausted its power and may not thereafter reverse the decision previously made.

Finally, the board attempted to justify its action by distinguishing between the revocation of a license and its "cancellation," thus impliedly conceding that it had no power to "revoke" except for grounds stated in section 10(a) after notice and hearing. The board argued that it had the power to "cancel" petitioners' licenses because section 10(b) provides that at anytime after two years following the "revocation or cancellation" of a license the board may reissue same. But, concluded the court, it is not reasonable to assume that the legislature, after particularly specifying the grounds on which a license can be revoked, intended by such mere use of the words "revocation or cancellation" to distinguish between the two and thus authorize an evasion of the provisions of section 10(a) by designating the process of annulment of the rights of a licensee as cancellation rather than revocation, especially since "cancel" is defined by Webster as meaning "to revoke or recall."

Accordingly, the judgment of the trial court directing the board of examiners to annul the order canceling the petitioners' licenses to practice chiropractic, and to refrain from interfering with their practice, was affirmed.—*Aylward v. State Board of Chiropractic Examiners, 172 P. (2d) 903 (Calif., 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Preoperative and Postoperative Care in Major Colonic Surgery. S. T. Ross.—p. 910.

Perforation of Duodenal Ulcer.—Graham reports 130 consecutive cases of acute perforation of a duodenal ulcer. Two patients refused operation, 2 were moribund on admission and 1 died before the diagnosis was made. Of the 125 operated on 8 died. The cause of a patient's serious clinical state following perforation of a duodenal ulcer is not the bacterial peritonitis, but the nutritional and biochemical imbalance associated with shock. Adequate correction of these disturbances decreases the mortality. An operation should deal in the most simple manner with the lesion responsible for the emergency. Gastroenterostomy and gastric resection have no place in this management. Fibrin is responsible for the closure of all gastrointestinal perforations. A free or attached omental graft held in position over the perforation by three sutures results in the gross formation of fibrin to close the perforation. Drainage of the abdomen at the time of closure of the ulcer is unnecessary.

Anesthesia: XXI. n-Propyl Methyl Ether as Inhalation Anesthetic in Man: (Preliminary Report). Mary Louise T. White, S. M. Shand and J. C. Krantz Jr.—p. 663.

Atelectasis During Operations on Upper Urinary Tract.—Faulconer and his co-workers report the occurrence of 8 cases of pulmonary atelectasis in a series of 85 operative procedures on the upper urinary tract in an army hospital. The atelectasis developed in each case in the contralateral lung. The only etiologic factor common to every case was the lateral position, resulting in unphysiologic cramping of the dependent lung. A wide variety of anesthetic agents and methods was used and seemed to have no important bearing on the postoperative pulmonary complication. No patient received prophylactic carbon dioxide-oxygen hyperventilation. The suggestion is made that an important point in prophylaxis is the shifting of the patient's position to the operated side at frequent intervals. The most satisfactory treatment is bronchoscopic aspiration.

Effect of Quality of Illumination on Results of Ishihara Test. L. H. Hardy, Gertrude Rand and M. Catherine Rittler.—p. 685.
Cyclofusional Movements. K. N. Ogle and V. J. Ellerbrock.—p. 700.

Neutralizing Antibody Test for Toxoplasmic Choroiditis.—Johnson describes a neutralizing antibody test for Toxoplasma. Thirty-two selected patients with chorioretinitis were tested; 20 of these gave positive reactions to the neutralizing antibody test. Cerebral calcification in patients who had toxoplasmosis with chorioretinitis was not observed when the age at onset was known to be over 15 years. If the disease was present at birth, calcification was evident. A mother with reactivated toxoplasmic choroiditis and a woman who was probably congenitally infected each gave birth to a normal child. Two children probably infected congenitally with toxoplasmosis had younger siblings-german with antibody protection but no demonstrable infection. A case of chronic toxoplasmosis is described in which a quiescent chorioretinal lesion became activated during each of three pregnancies.

Ascorbic Acid Metabolism.—Investigators in the field of nutrition usually consider that a fasting blood plasma ascorbic acid level of 0.6 mg. per hundred cubic centimeters is the lowest level consistent with normal ascorbic acid metabolism. Study of the fasting blood plasma ascorbic acid levels of 372 young Canadians gave values below 0.6 mg. per hundred cubic centimeters in 55 per cent and 0.25 mg. in 19 per cent. It was found that a great change in the intake of ascorbic acid will reflect itself in the fasting blood plasma ascorbic acid content in one to two weeks. Studies on the effect of relatively constant levels of intake of free ascorbic acid over periods of six to eight months revealed that with an average daily intake of 7.9 mg. the average fasting plasma level was 0.22 mg., with an intake of 22.3 mg. it was 0.26 mg., with 62.5 mg. it was 0.75 mg., with 78.3 mg. it was 0.87 mg. and with an intake of 437.5 mg. the blood plasma level was 1.49 mg. While every effort should be made to conserve the ascorbic acid content of foods in their preparation, cooking and serving, a small number of foods if taken each day will supply the major portion of the recommended amount of ascorbic acid These foods and the daily amounts required are set out in a table.

Primary Endothelioma of Pleura. H. Weissman.—p. 562.
Tuberculosis in Greece: Present Conditions and Future Considerations. P. A. Theodos.—p. 571.

Streptomycin in Tuberculosis.—This report by Pfuetze and his associates is concerned with 30 cases of pulmonary tuberculosis in which streptomycin was administered for from two to six months. With few exceptions the patients had tuberculosis that was progressive or did not respond to rest in bed. The daily dose varied from 1 to 4 Gm. It was divided into doses which were given every three to six hours by intramuscular or deep subcutaneous injection. It was found that streptomycin resembles other modern antibacterial agents in suppressing the multiplication of sensitive organisms without complete eradication of the infection. As a result there is a tendency for the disease to recur following cessation of streptomycin treatment. The author's believe that streptomycin may help in conjunction with other forms of treatment but that it should not be regarded as a substitute for well established forms of treatment.

*Studies on Toxicity of Influenza Viruses: I. Effect of Intracerebral Injection of Influenza Viruses. Gertrude Henle and W. Henle.—p. 623.
Id.: II. Effect of Intra-Abdominal and Intravenous Injection of Influenza Viruses. W. Henle and Gertrude Henle.—p. 639.

Toxicity of Influenza Viruses.—The Henles found that intracerebral injection of preparations of influenza viruses into mice led to tonic and clonic convulsions and death in tetanus, usually within twenty-four to seventy-two hours. Microscopic examination revealed destruction of the ependymal lining of the ventricles as the dominant finding. Propagation of the influenza viruses in the central nervous system could not be demonstrated. They concluded that the neurologic reactions were the result of toxic action rather than of virus propagation. The toxic agents could not be separated from the infectious particles by the use of such technics as differential high speed centrifugation, adsorption onto and elution from chicken red cells and precipitation by protamine. The toxic effect of influenza A virus preparations was specifically neutralized by anti-influenza A and not by anti-influenza B serum, and conversely. In addition, antigenic differences were noted between two strains of influenza A virus by this method of testing.

Cerebral Palsy Problem. C. H. Frantz.—p. 1489.
*Adhesive Strapping for Low Back Pain. H. J. Schaubel.—p. 1492.

Surgery of Pancreas and Lower Biliary Tract.—Crile reviews 8 cases of pancreatic lithiasis, in 5 of which various types of pancreatolithotomy and pancreatoduodenectomy were done. Pancreatic lithiasis is probably a result of chronic recurring pancreatitis, for which there is no satisfactory treatment, its cause being unknown. Diagnosis of carcinoma of the body of the pancreas is difficult at a time when it is still curable. Carcinoma of the head of the pancreas and lower bile ducts carries a more favorable prognosis than carcinoma of the body. If operation is performed before the liver suffers irreparable damage, chances of survival are good.

Adhesive Strapping for Low Back Pain.—Schaubel employed an adhesive support supplemented with tongue blade splints for the treatment of low back pain and low back injuries which require temporary immobilization.

Endocrinology and Treatment of Functional Uterine Hemorrhage. E. C. Hamblen.—p. 497.
Clinical Experiences with Diphtheria. C. E. Thompson.—p. 502.

Cystic Fibrosis of the Pancreas.—Kennedy describes the chief aspects of cystic fibrosis of the pancreas on the basis of 28 cases. Evidence of chronic infection of the respiratory tract, steatorrhea and failure to gain weight are the most constant symptoms, and their presence either alone or in combination in an infant or young child should arouse the suspicion of cystic fibrosis of the pancreas. Recent studies indicate that, although the diet should consist predominantly of protein food, the condition of patients may be better if a moderate amount of fat and carbohydrates is included. Protein milk, cottage cheese, bananas, bacon, lean meats, puréed vegetables, orange juice, tomato juice, soybean muffin, honey and grated apple are the foods more commonly employed to build the diet. To this list may be added whole milk, cream and butter.

Tuberculosis in Mental Schools and Hospitals in Ohio. M. W. Garry.—p. 1265.

Schizophrenia in Children.—Schumacher reports the histories of 7 children who developed schizophrenia before their thirteenth year. He deduces from these case studies that all forms of adaptation are involved and that pathologic disturbance occurs at every level of nervous system function—vegetative, motor, perceptive, intellectual, emotional and social. All integrative functioning is disturbed, but this will manifest itself according to the developmental age of the child. Schizophrenia in children is not to be diagnosed on the resemblance of a few symptoms to those almost diagnostic in the postpuberal age groups. Delusions and hallucinations are rare in children. Only 1 child showed such symptoms. Symptoms vary from one age level of development to another but in all cases represent a severe distortion of the entire personality. The prognosis in this series does not seem to be too favorable, but other recent case reports indicate that up to 50 per cent of schizophrenic children may show improvement.

Vitamin C in Traumatic Shock.—Holmes found that when 500 mg. of vitamin C was given by mouth to patients of average weight within the hour before operation there was clinical evidence of a considerable decrease in traumatic shock. In tooth extraction oral administration of 500 mg. of vitamin C within the hour before operation is remarkably successful in preventing shock or postoperative weakness. Immediate administration of 500 mg. or more of vitamin C to 35 patients who had sustained varied accidents at coal mines seemed to increase shock resistance and to improve their condition. Intravenous injections of 500 or 1,000 mg. of vitamin C in sterile, buffered solutions was used preoperatively and postoperatively in a series of 50 major abdominal operations with excellent results.

Reactions to Lumbar Puncture.—Redlich and his associates investigated the relative significance of purely physiologic and emotional factors in the pathogenesis of the postlumbar puncture syndrome. One hundred hospitalized psychiatric patients were punctured routinely. From this group were excluded all persons with gross deterioration, extreme psychotic states and contraindications to spinal puncture. Alternate patients were punctured with number 16 and number 22 gage needles. The patients' knowledge of the procedure and its underlying principles proved as low as their anticipatory anxiety was high. About half of the patients had heard of someone who had undergone the test and 23 per cent knew of ill effects in others. The author concludes that drainage is the most significant factor in the production of symptoms following lumbar puncture, outweighing by far the small contribution of anxiety, hypochondriasis and other emotional elements.

*Statistical Study of Delivery with Continuous Caudal Analgesia, as Compared with Other Methods. S. D. Collins, F. R. Phillips and Dorothy S. Oliver.—p. 1713.

Delivery with Continuous Caudal Analgesia.—Collins and his associates compare the results of continuous caudal analgesia in 2,516 mothers and a control group of 1,024 mothers delivered with the usual anesthetics and sedatives. There was no evidence of danger to the mothers delivered with continuous caudal analgesia, although a third of them showed a considerable drop in systolic blood pressure during the administration of the drug. Complete relief was obtained for 90 per cent of the mothers. The postpartum action of the uterus was better in the caudal than in the control group. There were fewer stillbirths and fewer deaths of infants during the first week of life in the caudal than in the control group.

Primary Retroperitoneal Tumors.—Donnelly directs attention to the primary retroperitoneal tumors, which are believed to originate from remnants of the urogenital fold. The tumors occur twice as often in men as in women. They are predominantly malignant, sarcoma being the most common type. The symptoms in the early stages are vague and are primarily gastrointestinal in nature. As the mass increases in size the symptoms are those resulting from pressure on adjacent organs. The diagnosis is made by exclusion. Retrograde pyelography showing characteristic findings of ureteral displacement and gastrointestinal x-ray series for excluding tumors of the gastrointestinal tract are the most valuable diagnostic aids. The treatment of choice is operative intervention with as wide excision of the tumor as possible.

Reconstruction of Bony Defects of Face.—Macomber gives a general survey of the problem of restoring facial bones functionally and of correcting contour defects cosmetically. On the basis of personal experience in a large number of cases he says that results from foreign substances have been consistently bad and that the use of all such substances should be abandoned. Homogenous preserved cartilage has its useful place, particularly in replacing lost ear cartilage. Fat is practically useless except as a local attached subcutaneous pedicle for small depressions. Fascia lata is sometimes preferable for shallow depressions and probably serves more safely and dependably than deepithelialized skin. Iliac cancellous bone is a singularly dependable, utilitarian, safe, and satisfactory tissue for correction of defects.

Causalgia.—Ulmer and Mayfield present data on 75 patients with causalgia. They employed surgical procedures on 72 of their patients. The sympathectomy must be complete. With lesions involving the upper portion of the sciatic nerve removal of the sympathetic chain as high as the eleventh dorsal ganglion may be required. For lesions of the upper extremity preganglionic operation is adequate. Procaine block of the appropriate chain is a necessary diagnostic procedure, but as a therapeutic agent it has not been effective. Resection of the injured segment of nerve will provide relief. Neurolysis and periarterial sympathectomy are ineffective. Sympathectomy should be done as soon as the diagnosis is established to prevent the psychic trauma of prolonged pain and crippling joint stiffness. Causalgia has been noted only with incomplete nerve lesions. Recovery of function is often rapid after relief of pain. Consequently, primary neurorrhaphy is rarely indicated.

Treatment of Painful Spondylolisthesis.—At the University of Iowa the surgical treatment of painful spondylolisthesis consisted in the use of the Hibbs technic or a combination of the technics of Albee and Hibbs as described by Steindler. They are used only when there is assurance that the results will be superior to those of conservative treatment. Puig Guri reviews the end results of 60 cases after a long term follow-up. Complete relief was obtained in 41.1 per cent of the patients treated conservatively and in 69.2 per cent of the cases treated with spinal fusion. No progression of the deformity was observed after the treatment by means of braces or posterior spinal fusion. Surgical procedures that endanger the life of the patient are not justified. The presence of a sciatic pain together with local spinal symptoms does not necessarily mean that permanent relief cannot be obtained unless the disk is removed or curetted. In 55.5 per cent of the cases presenting such a clinical picture, complete relief was obtained either by conservative means or after the fusion of the posterior spine. In advanced cases of spondylolisthesis the spontaneous fusion of the anterior spine after destruction of the intervertebral disk did not constantly produce complete relief of the symptoms. On the other hand, following the application of a spinal support or the surgical fusion of the posterior spine, all the symptoms disappeared.

Vascular Injuries.—Thomas and Pittman review observations in 28 cases of injuries to the major arteries seen in the European Theater of Operations. Twelve cases of sudden interruption of the superficial femoral artery or its ligation for traumatic aneurysm resulted in gangrene only if the profunda femoris area was badly damaged. Gangrene occurred in 6 of these cases, but in 5 of the 6 cases there was an associated comminuted fracture of the femur. In 7 cases without fracture gangrene occurred only once. Six cases of sudden popliteal artery division resulted in gangrene, as did also the only case of common femoral artery division. Two cases of ligation of the axillary artery did not result in gangrene. Ligation of the posterior tibial artery was tolerated well. Lumbar sympathetic block may have influenced the level of gangrene in the lower extremity, but in no instance did it seem to influence the occurrence of gangrene. Of the 9 traumatic aneurysms of large vessels 8 were arterial and only 1 was arteriovenous.

Intracranial Pneumograms.—Schneider thinks that intracranial pneumography is a relatively safe and accurate means of diagnosing and localizing intracranial lesions, provided the procedure is in competent hands with due precaution against the recognized dangers. In children it may be of particular value in view of the often unsatisfactory histories and even examinations. Illustrative cases are presented.

Acclimatization to Anoxia.—Since mountain expeditions are handicapped by difficult terrain, adverse climatic and living conditions and inadequate laboratory facilities, a low pressure chamber was used in this study. Ascent was made at the rate of 2,000 feet a day to 9,000 feet, at 1,000 feet a day to 15,000 feet and at 500 feet a day thereafter. Usually the ascent was made gradually during a two hour period in the evening. None of the subjects were seriously affected by altitude below 20,000 feet, and at no time was the clinical picture of "mountain sickness" observed. All 4 noted a gradual decline in appetite, reflected not only in reduced caloric intake but also in an average weight loss of 6 pounds during the last two weeks of the study. Cyanosis increased during work. Dyspnea on exertion was the chief complaint. The 4 subjects did not acclimatize to altitude either as completely or as rapidly as do mountaineers. The reason for this is not clear but may be attributed to the confined quarters, which made sustained and strenuous exertion impossible.

Subdiaphragmatic Abscess.—Adams suggests that in gastrointestinal, acute biliary and traumatic surgery the serious complication of subdiaphragmatic abscess may be eliminated by careful walling off of the area, by complete aspiration with suction of all contents spilled into the peritoneum and from over the dome of the liver, by instillation of penicillin into these areas at the close of the operations and by an adequate course of penicillin and sulfadiazine postoperatively.

*Effect of Penicillin on Vaccinia Virus. M. A. Gohar and A. Bashatli.—p. 115.

The Heart in Severe Anemia.—Gelfand says that in Europeans heart failure due to anemia is not frequent because they usually seek medical aid relatively yearly, so that the anemia is usually corrected before the heart begins to fail. Africans frequently do not receive medical attention until the anemia is quite severe. When admitted to the hospital their hemoglobin may be as low as 10 or 20 per cent. Among 42 cases of heart disease which the author treated in a native hospital there were 7 with congestive heart failure due to anemia. Moribund patients are often admitted for whom little hope can be entertained. However, even when the anemia is severe and the symptoms are distressing recovery often follows with the correct treatment. To the severely ill a transfusion of 500 cc. of blood should be administered slowly. The patient is given ½ pound of raw or slightly cooked liver a day, together with iron tablets by mouth. Yeast also is administered. Some patients have been given three or four blood transfusions. The cardiac condition requires rest with the patient semirecumbent.

Effect of Penicillin on Vaccinia Virus.—Suspecting that the use of glycerin with vaccine lymph may be responsible for some anomalous results, Gohar and Bashatli thought that in the purification of the lymph advantage might be taken of the resistance of viruses and sensitiveness of cocci and other gram positive organisms to penicillin. They found, however, that glycerin is superior to penicillin in the purification of vaccine lymph. Penicillin seems to be capable of inactivating the vaccinia virus. When it is injected into rabbits within twenty-four hours after inoculation with a rabbit-passed vaccinia virus, the typical lesions of vaccinia fail to develop. The authors suggest that penicillin be tried in the treatment of variola.

Thrombosis of Superior Vena Cava. E. T. Renbourn.—p. 257.
*Atelectasis as Complication of Pulmonary Lobectomy. I. R. Gray.—p. 263.

Extrapleural Pneumothorax in Pulmonary Tuberculosis.—Reid reports 54 cases of pulmonary tuberculosis with extrapleural pneumothorax performed during the period of 1938 to 1944. Eleven of the 54 patients developed tuberculous infection, and 4 developed infection due to other bacteria in the extrapleural space. Thirty-seven patients left the sanatorium with sputum conversion. Eight patients died, 1 directly as the result of operation, 4 because of the spread of the disease soon after operation and 3 because of the remote spread of the disease after four years. Eleven of 17 patients traced over four years obliterated their extrapleural space. The remaining 6 with persisting spaces did well clinically. These results suggest not only that extrapleural pneumothorax may be a life saving measure to tide the patient over and make him safe for a thoracoplasty, but that, as a preliminary to thoracoplasty, avoiding the risk of bronchogenic dissemination, extrapleural cutaneous fistulas and shock, extrapleural pneumothorax is consistent with good general condition, working capacity and freedom from cough and sputum even after a lapse of four years.

Atelectasis Complicating Pulmonary Lobectomy.—Postoperative atelectasis occurred in 23 of 90 cases of suppurative disease in an unselected series of 106 pulmonary lobectomies which were analyzed by Gray. There was not one postoperative atelectasis in the remaining 16 cases in which lobectomy was performed for nonsuppurative condition. Twenty-two of the 23 cases of atelectasis were of one of the remaining lobes on the side of the operation and there was 1 case of contralateral atelectasis of the lower lobe. Three of the 23 cases of atelectasis became permanent. The presence of pleural adhesions at the time of operation was associated with a considerably reduced incidence of postoperative atelectasis. The incidence of atelectasis was increased when more than one lobe had been removed. Examination according to age revealed that in children the likelihood of atelectasis was twice as great as in adults. Cases in which the amount of sputum produced daily was more than 1 ounce had a higher rate of atelectasis than those with less. The sex of the patient, the season of the year and the duration of pleural drainage had no influence on the occurrence of atelectasis. Artificial production of adhesions with silver nitrate, iodized talc or kaolin, preoperative breathing exercises and postural drainage are recommended for preoperative prophylaxis of atelectasis. Treatment of atelectasis consists in tracheal intubation under local anesthesia with suction by means of a fine catheter; if no benefit results, early bronchoscopy is suggested.

Study of Intragastric Temperature and of Its Modifying Factors. M. J. Mašek.—p. 215.

Cancer of Rectum and Contact Roentgenotherapy.—Gros reports 70 inoperable cases of cancer of the rectum in patients admitted to the cancer center in Montpellier, France, during the period of January 1944 to January 1946. Contact roentgenotherapy with a total dose of 9,000 to 60,000 was applied to 28 of these patients with cylindricoepithelioma. Death resulted from hemorrhage in 2 and recurrences took place in 2. Sixteen are alive in whom local control examination has not been performed. An apparent cure is suggested in 8 patients by the satisfactory general condition, by their freedom from pain and by negative biopsies; the rectal wall in 4 of these patients does not present any fibrous cicatrization. It is still too early to compare the surgical indications with those of contact roentgenotherapy.

Localized Typhus Epidemics Among Prisoners of War in France.—After an epidemic of 97 cases in February 1945 and 318 cases observed between April and July, exanthematous typhus disappeared from France in August and September. It reappeared in October and November among German prisoners of war. The dominating feature was the almost simultaneous appearance of typhus in the Bordeaux area and in Marseilles, without recent influx of infected persons. It would therefore appear to constitute a local reappearance of the disease among persons in a state of low resistance. This suggests that similar manifestations in other parts of the country must be anticipated.

Thresher's Disease.—Hoffmann describes a disorder which developed in persons who had inhaled dust while working at threshing machines. The threshing had been done in rather confined sheds, and the grain in question had been harvested while damp and had become gray. The patients had fever for from one to five days, cough, severe sweating, headaches, a feeling of extreme weakness and unsteadiness when attempting to stand or walk. The examination of barley that had caused several cases of thresher's disease revealed a fungus that has been known to produce a condition characterized by a dizzy swaying. It is assumed that thresher's disease is likewise caused by fungi. Threshing in the open air or devices for the suctioning off of dust might help to prevent attacks of thresher's disease.

Shoveler's Disease.—Wetzel directs attention to the occurrence of avulsions of the spinal processes in the course of exertions, such as pitching in farm work, by persons who are unaccustomed to hard physical labor. To illustrate this so-called shoveler's disease he presents the case of a youth, aged 18, a copper-engraver by trade, in whom avulsion of a spinal process venth cervical) took place while he was engaged in farm rk. His complaint was pain between the shoulder blades. ere was sensitivity to pressure in this region, and forward d sideward lifting of the arms caused pains. Such patients uld refrain from the exertion that caused the avulsion for out four weeks.

nlargement of Operative Field of Vision in Intra-Abdominal Surgery. L. E. Cardoso.—p. 1.

Visibility of Operative Field in Intra-Abdominal perations.—Cardoso reports increased visibility of operative ld in 67 patients who had intra-abdominal operations after an raperitoneal injection of 20 cc. of venous blood. The best sults were obtained when the injection was administered by following technic: twenty-four hours before the operation patient is given a purgative dose of castor oil or a saline thartic; twelve hours later 20 cc. of the patient's blood is thdrawn from a vein and is slowly injected in the midabdomil line intraperitoneally. This is followed by expulsion of gases d feces and consequent intestinal collapse which lasts for ten fifteen hours, during which period the visibility of the intradominal exposure is much enlarged. The injection is harmless d the blood is reabsorbed within twenty-four hours.

Cholesterol Content of Human Aorta.—Faber determined the cholesterol content of the aorta of 29 normal persons between the ages of 18 and 73 and compared it with the concentration of cholesterol in the blood serum. The increasing amount of cholesterol found in the aorta in the higher age groups was independent of the serum cholesterol concentration. The cholesterol content of the aorta of 19 patients with coronary occlusion between the ages of 32 and 78 and of 17 patients with hypertension and early atheromatosis between the ages of 49 and 65 was determined. In contrast to the normal persons, a number of younger patients showed an increase in the cholesterol content of the aorta above the value found in much higher age groups. This increase resulted from an increase in the concentration of cholesterol in the blood serum above the normal in cases of xanthomatosis with persistent hypercholesterolemia. In hypertension the same increase in the cholesterol content of the aorta was found in the absence of hypercholesterolemia. It is suggested that hypertension induces a change in the wall of the vessel with a higher affinity for cholesterol and with greater deposits.

*Histology of Asbestosis. L. Noro.—p. 53.
Studies on Bacteriophage of Various Strengths with Special Regard to Its Effect on B. Coli in Transmigration Culture. G. Fischer.—p. 60.

Asbestosis.—Two workers in an asbestos factory died under circumstances which indicated that the cause of death was their trade. When the workers of this factory were examined roentgenologically asbestosis was found in 65 per cent of the 167 workers examined. The microscopic picture of asbestosis is characterized by a reaction caused by the needles in the tissue, which becomes manifest in exudate cell infiltration, accompanied by numerous giant cells containing foreign particles and an increase of interstitial connective tissue and fibrosis. Noro is inclined to think that in the pathogenesis of asbestosis the mechanical factors are the most important, although the chemical factors may have some significance in a later phase.

Book Notices

A Textbook of Biochemistry. By Philip H. Mitchell, Ph.D., Robert P. Brown Professor of Biology, Brown University, Providence, R. I. Cloth. Price, $5. Pp. 640, with 84 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42d St., New York 18, 1946.

This book is excellent for the choice and presentation of subject matter, for the simplicity and fluency of language and for the lucidity of style. It is a very readable textbook. The author has succeeded admirably in embodying the newer knowledge of biologic chemistry without sacrificing and pushing to the background the older knowledge that still remains basic and fundamental. He is abreast of the times in fact and in theory. Even the most recent knowledge of antibiotics receives a chapter. As a rule the smaller textbooks in biochemistry suffer from the fact that the subject matter is either insufficiently treated or that it is so condensed as to omit important points needed for full comprehension of the topic in discussion. Such gaps in subject matter are happily absent. Small textbooks also suffer from the fact that difficult topics are handled inadequately so that the student loses the full significance of important biochemical concepts. In this book hydrogen ion concentration, acid and base regulation, the chemistry of respiration, biologic oxidations and redox potential are presented in a satisfying, clear and illuminating manner. One senses that the author is a master not only of his subject but also of pedagogy. He brings a fresh and vigorous point of view to his subject. Throughout the physiologic angle is emphasized. Descriptive matter is therefore at a minimum and presented only as far as it is necessary to comprehend the dynamics of the biologic organism. Major space is allotted to function. The author is dominated by the belief that the real chemistry of life lies in an explanation of metabolism. He presents his subject not as a still picture but as an ever changing motion picture. The activity of enzymes, vitamins and hormones and the intermediate reactions of metabolism, both in its anabolic phase and in its catabolic phase, consequently receive ample stress. The interconversion of foodstuffs in metabolism is studied as the groundwork for adequacy and balance in diet. Enzymes, vitamins and intermediate metabolism of lipids, carbohydrates and proteins are all linked in the process of supplying proper nutrition to the biologic organism.

The author occasionally steps out of the role of a formal textbook writer and assumes the role of dramatizer. This role adds interest to the book. Here is an example of vivifying scientific fact by dramatization:

> Bio-oxidation is the subtitle of the drama of life. It is the central theme of every physiological story. It is characteristic and cannot be closely imitated in nonliving systems. It is one process which must go on if life is sustained and its failure is the infallible sign of death.
>
> In spite of all that is known about bio-oxidation, it is a drama of which the plot is still unsolved. The biochemist is a stagehand. His position in the wings has enabled him to get acquainted with some of the actors (enzymes), to see the properties (foodstuffs) going on the stage, to catch snatches of conversation and hear stage effects (activity of certain enzymes) during the play, and to know that the play goes to a successful conclusion (growth, maintenance, production, of heat and work, excretion of H_2O, CO_2 and other waste products) unless there are missing (malnutrition) some of the stage properties or unless hoodlums (invading organisms) interfere. But how the plot works out he does not know. One guess is worth considering as a tentative explanation of a part of the problem. It is fairly apparent that cellular enzymes are not generally in haphazard positions but are definitely oriented in protoplasmic organization, as are the members of a chorus or a ballet on the stage, so that they can perform as a unit. This guess is based partly on the orderly sequence of oxidation-reduction reactions proceeding as a unit, although involving many enzymes, and partly on the well known effects of injury. Slight mechanical injuries may depress the oxidation in a cell and severe ones abolish it. Incidentally, the converse is also true. Depressed oxidation, as in oxygen deprivation, causes cytological disorganization, reversible in early stages but eventually fatal. Pursuing the allegory a little further, the cell is not only the stage but is the training school, producing the actors, and the shop, producing the stage setting. The cell synthesizes its enzymes and its protoplasmic materials.

The book is designed as a first course in biochemistry. It may well be read by the advanced student for the uniqueness of presentation and for its refreshing points of view. To the physician and to the advanced medical student the book offers a refresher course and an easy road to the newer knowledge of biologic chemistry.

Insight and Personality Adjustment: A Study of the Psychological Effects of War. By Therese Benedek, M.D. Cloth. Price, $4. Pp. 307. Ronald Press Company, 15 E. 26th St., New York 10, 1946.

Dr. Benedek in this book attempts to present, against a backdrop of war and peace, the basic dynamisms of human relationships. Her thesis is divided into four parts. Part I, on the individual, outlines, in conformity with the orthodox freudian doctrine, the mechanisms of personality growth, maturation and psychosexual development. Part II, on the soldier, deals with the influences of the sudden and deep-going change in the personality brought about by army life: the stresses of induction, acclimatization and demobilization. Part III, on the family in war, is the major essay, 140 pages devoted to such divers subjects as the relationship which exist between sons (soldiers) and their mothers, fathers, siblings, wives and children; mourning for the soldier and the disabled veteran. Part IV, on men, women: the changing sexual mores, is a critique of sexual behavior which highlights the social and sexual problems of femininity in recent years.

It is difficult to avoid the impression that Dr. Benedek's exposition is not categorical and deductively reasoned from a priori theory. Her "soldiers" of World War II were some fourteen million single, married, widowed and divorced, young, middle-aged and old individuals. They were enlisted and inducted from every walk of civilian life. Their economic, social, educational and psychologic status ranged over many cultural and subcultural spectra. In the light of this, in writing of their war born emotional vicissitudes, one cannot validly create an amorphous stereotype and by rhetorical extrapolation give a scientific account of its psychosocial life.

Any single investigator's data would be too few to permit drawing first hand conclusions of the problems of adjustment of a generation, let alone an explanation of the responsible operative dynamics of a culture in flux. The psychologic problems in the phenomena of war and peace are worthy of a more scientific study.

Lehrbuch der Geburtshilfe und Gynäkologie. Herausgegeben von E. Anderes, H. Guggisberg, und Th. Koller. Band I: Lehrbuch der Gynäkologie. Bearbeitet von Prof. Dr. H. Guggisberg, Prof. Dr. E. Hintzsche, Prof. Dr. F. Ludwig, P.D. Dr. C. Müller, und Prof. Dr. W. Neuweiler. Herausgegeben von Prof. Dr. Hans Guggisberg, Direktor der Universitäts-Frauenklinik, Bern. Cloth. Price, 72 Swiss francs. Pp. 717, with 354 illustrations. S. Karger, Holbeinstrasse 22, Basel; 215 Fourth Ave., New York 3, 1946.

Regarding this excellent and most comprehensive work on gynecology, the foreword furnishes interesting information. The directors of the women's clinics of the Universities of Basel, Bern and Zurich determined to compile and issue a new work on gynecology and obstetrics in the German language. This textbook of gynecology represents the first of three volumes comprising this work, the second to be a textbook of obstetrics and the third a textbook of obstetric operations.

Hans Guggisberg of Bern has served as editor and chief author of this volume on gynecology and has sought and directed most capably the assistance and collaboration of a number of his associates, each of whom was chosen for his own special knowledge of subjects constituting various sections of this first volume.

When the other two volumes appear, to be treated similarly under the direction of E. Anderes of Zurich and T. Koller of Basel with the help of colleagues, we shall have an authoritative and representative exposition of gynecology and obstetrics as practiced in Switzerland. It is perhaps to be regretted that volume III is not planned as a work on gynecologic as well as obstetric operations. Gynecologic operative procedures are not discussed in the volume now being reviewed. Such a gap leaves one with the feeling that the work will be seriously incomplete, whereas it would be logical to include operative gynecology in volume III instead of leaving this to deal with operative obstetrics alone.

This first volume is well printed and in excellent style, and the illustrations are superb, particularly the reproductions of color photographs. American readers will take exception to drawings showing pelvic examinations and various other procedures being carried out with ungloved hands, and this is inexcusable. However, the technical points being thus illustrated are capably shown. There are, in fact, other items with which our views are not in accord, such as the use of seaweed or similar tents (laminarstifte) for dilation of the cervix; but such criticism is merely faultfinding in view of the general excellence of the book.

The subject matter of gynecology is thoroughly covered from the fundamentals of physiology, anatomy and histology to major pathologic conditions and includes a good section on sterility.

The entire work should be of greatest value to German speaking people particularly since the almost complete cessation of similar works in Germany due to the war. Elsewhere it will be found useful not only as representative of the Swiss point of view but also as an extensive work on gynecology, well written, well edited and well published.

Le fibro-myome utérin: Statistiques, critiques et commentaires sur *une série personnelle de 1,300 cas dont 547 inédits. Fibromatose expérimentale, physiologie de l'ovaire irradié.* Par J. Ducuing, professeur de clinique chirurgicale à la Faculté de médecine de Toulouse. Paper Price, 735 francs. Pp. 537 with 156 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris, 6^e, 1946.

This book is based not only on a review of the literature on uterine fibromyomas but also on the author's extensive clinical experience with 1,300 cases and on his experimental work. The author is both a surgeon and a radiotherapist, so that he is able to evaluate properly the merits and disadvantages of surgery and radiotherapy in the treatment of uterine fibromyomas.

In the first few chapters the author analyzes his personal cases. In succeeding chapters he discusses the composition of uterine fibromyomas, including the fibrous elements, the muscle tissue, the endometrium associated with fibromyomas, the blood supply, the condition of the ovaries in the presence of these tumors, the physiology of the uterine cycle, ovulation, the mechanism of abnormal bleeding in cases of fibromyomas, the clinical forms of these neoplasms, diagnostic aids, errors in diagnosis and the indications and contraindications for treatment; medical, surgical, radiation and endocrine therapy; the results of treatment, complications, mortality and morbidity and finally the author's evaluation of radiotherapy for fibromyomas. In the discussion on treatment the author takes up surgical operation versus x-ray treatment versus radiation therapy, and in dealing with operative intervention he discusses myomectomy, abdominal total and supravaginal hysterectomy, vaginal hysterectomy and retention or removal of the ovaries. In addition the vast literature on the subject of uterine fibromyomas is reviewed. Hence the work is in reality an extensive reference work on the subject. It is well written, easy to read, abundantly and beautifully illustrated and printed on excellent paper. The book should be in the library of every one interested in the subject of uterine fibromyomas. Gynecologists, surgeons, radiation therapists and endocrinologists should possess a copy of this book.

Laboratory Instructions in Biochemistry. By Israel S Kleiner, Ph.D , Professor of Biochemistry, New York Medical College, Flower and Fifth Avenue Hospitals, New York, and Louis B. Dotti, Ph.D., Chemist, St Luke's Hospital, New York. Second edition. Loose-leaf. Paper. Price, $2.50. Pp. 245, with 8 illustrations. C. V. Mosby Company, 3207 Washington Blvd , St. Louis 3, 1946.

This laboratory manual in biochemistry includes chapters on physical chemistry, carbohydrates, lipids, proteins, tissues, milk, digestion and qualitative and quantitative analysis of blood and urine. In addition there is a chapter on toxicology dealing with qualitative tests on methyl alcohol, phenol, cyanide, strychnine and other poisons in tissues. There are many of the newer analytic methods for blood and urine analysis and many modifications of fundamental experiments. Some quantitative work on cerebrospinal fluid is included and also an excellent section on reagents and solutions. The chapter on food analysis included in the first edition was omitted. This manual is written primarily for the medical student who has to apply basic principles in biochemistry to the practice of medicine. The experimental procedures are excellently described, but there is inadequate discussion of principles involved, and no structural formulas are used. The volume can be used satisfactorily for students in biochemistry in medical and dental schools.

Psychotherapy in General Medicine: Report of an Experimental Postgraduate Course. By Geddes Smith. Paper. Price, 25 cents; free to *medical schools, medical societies and public agencies.* Pp. 38. Commonwealth Fund, 41 E. 57th St., New York 22, 1946.

This is a brief yet comprehensive account of a two weeks postgraduate course in psychotherapeutic medicine. The Commonwealth Fund and the University of Minnesota during April 1946 sponsored this training for twenty-five selected physicians who represented the practice of medicine under varying conditions in mid-Western communities of assorted size. It was the consensus that the overall purpose was accomplished: to sensitize doctors to emotional problems in their medical practice.

The art of medicine, which assays and treats the whole man as an integrated unit, was the motif in the plan of the course. The teaching technics used included didactic lectures, seminar discussions and, most important, first hand clinical experience with the actual care of patients. The best teaching was done in the smaller section meetings, which stressed the clinical significance of the individual case. The general and special medical clinics of the university hospital furnished the kind of patient material with which every general practitioner is familiar; cases of long-standing distress—patients with the psychosomatic symptoms so typically representative of the persistently unwell. The major portion of the report describes in a diary fashion the manner in which the course evolved; among other lessons it was learned that flexibility is the sine qua non of medical pedagogy. In some instances predetermined methods had to be revised to fit the student physicians' needs more adequately. The gratifying result was that for the first time in their medical careers these physicians came to comprehend the meanings of dynamic psychiatry. Phenomena such as the doctor-patient relationship, the meaning of a psychoneurosis, the development of a normal personality, the dynamics of anxiety, the effect of emotions on physiologic functioning and the methodology of psychotherapy were analyzed vis à vis patient problems.

This report is an admirable protocol of an important experiment. It explicitly describes a brief training course in psychotherapeutic medicine and it implicitly points the way to better medical education for the nonspecialist.

L'epilessia sperimentale. *Di Giuseppe Moruzzi. I, Problemi di medicina sperimentale:* Raccolta di studi diretta da Giulio C. Pupilli. Paper. Price, 150 lire. Pp. 128, with 26 illustrations. Nicola Zanichelli, Piazza Galvani, Bologna, 1946.

The author, who has worked with Adrian in England, reviews his observations and those of others that deal with the oscillographic recordings of nerve impulses after faradic or strychnine stimulation of different portions of the central nervous system of animals. The book is illustrated by reproductions of tracings and is fortified by reference to more than four hundred articles, of which twenty-two are by the author. The presentation is in three parts: (*a*) general physiology, (*b*) special physiology and (*c*) the application of animal experiments to epilepsy in human beings. The author concludes that, because clinically and electroencephalographically the induced convulsions of animals resemble the spontaneous convulsions of patients, these experimental observations can be used to explain the neurophysiology and pathology of epilepsy. The monograph should be of interest to neurophysiologists.

Exercises in Electrocardiographic Interpretation. By Louis N. Katz, A.B , M.A., M D., Director of Cardiovascular Research, Michael Reese Hospital, Chicago Second edition. Cloth. Price, $6. Pp. 288, with 141 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1946

This edition differs from the first in that thirty-eight new cases have been substituted for old ones and the total number of cases has been raised from ninety to one hundred. The electrocardiograms are a representative group and in general are excellently reproduced. Descriptions of curves involve the use of many terms which are peculiar to the author and his associates. Correlations of electrocardiographic with clinical phenomena reveal more caution in making anatomic diagnoses from electrical data than is displayed in the author's companion volume "Electrocardiography." Correlations with necropsies are rare. The volume should be of use to the beginner.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF THYROTOXICOSIS IN PREGNANCY

To the Editor:—May thiouracil be used for thyrotoxicosis in or during *pregnancy?* If not, would iodine in the form of Lugol's solution be preferable and should thyroidectomy be planned to follow such giving of iodine? A woman aged 24, three months pregnant, has a basal metabolic rate of +30 and a pulse of 110 at rest. She is otherwise in good physical condition. Her fast pulse and nervous condition came on gradually before pregnancy but have become worse since pregnancy. Please discuss the treatment of thyrotoxicosis during pregnancy.

M.D., Minnesota.

ANSWER.—There is a difference of opinion concerning the use of thiouracil in the treatment of thyrotoxicosis during pregnancy. Some observers feel that it may injure the fetus and result in stillbirth, whereas others are of the opinion that it is just as safe to use the drug in women who are pregnant as in those who are not. There are not enough data at present to settle the question.

Thyroidectomy may be performed safely during pregnancy after adequate preoperative preparation. The danger of a miscarriage apparently is not greater following thyroidectomy.

The two questions that cannot be answered definitely at the present time are:

1. Is it safe to use thiouracil for preoperative preparation in pregnant women who have toxic goiters?
2. Is it safe to use thiouracil alone without operation in pregnant women who have toxic goiters?

There are many reasons for believing that toxic reactions from thiouracil are no greater in pregnant women than in nonpregnant women, but until there are enough data to answer this question definitely it is necessary to preserve an open mind.

TREATMENT OF CHRONIC CYSTIC MASTITIS

To the Editor:—Please discuss the treatment of chronic cystic mastitis.

M.D., West Virginia.

ANSWER.—The treatment of chronic cystic mastitis has become fairly well standardized, and little new can be added. A conservative regimen usually consists in wearing adequate uplift support for the affected breast. Thyroid in doses of ½ to 1 grain (32 to 65 mg.) daily has been helpful in some instances. The thyroid is supposed to aid in the elimination of water from the breast through normal channels. Administration of testosterone propionate has given variable results. Opinion has become solidified against the use of ovarian extracts or ovarian substitutes in large doses or continuously because of the doubtful relationship of endocrine stimulation to the development of carcinoma of the breast.

The consensus has been that little relationship exists between chronic mastitis and carcinoma of the breast, but some investigators have estimated that in 22 per cent of the cases of chronic mastitis in which surgical treatment is not carried out the predominant characteristics of extreme epithelial hyperplasia will develop and in from 20 to 30 per cent of these cases the lesions will become frankly malignant.

Nodular regions must be removed for microscopic examination, as clinical impressions are notoriously prone to be in error, even when knowledge and experience are extensive.

TOXICITY OF MECHOLYL BROMIDE

To the Editor:—A girl aged 6 years has received mecholyl bromide 0.2 Gm. daily almost continuously for three years as a stimulant to the smooth muscle of the colon. She has a moderate enlargement of the colon. Is there any risk involved in using this drug in such dosage indefinitely?

Walter G. Bernard, M.D., Detroit.

ANSWER.—Since the patient described in the query has apparently displayed no untoward reactions to the drug, there seems to be little danger in prolonging the drug indefinitely at the stated dosage. Mecholyl bromide is relatively nontoxic by oral administration, and there is no evidence of chronic toxicity with prolonged use: M. G. Peterman (J. *Pediat.* **27**:484 [Nov.] 1945) reports no unfavorable reactions to a continued dosage of 0.2 Gm. twice daily for sixteen months, while doses of 2 Gm. daily for three days were administered without toxic reactions.

PROLONGED ADMINISTRATION OF FERROUS SULFATE AND FERROUS GLUCONATE

To the Editor:—Would there be any harmful effect if a patient was to take ferrous sulfate and ferrous gluconate at the same time in average doses for two or three weeks?

M.D., Massachusetts.

ANSWER.—No. While the average adult oral dose for ferrous sulfate and ferrous gluconate is 15 or 20 grains (1-1.3 Gm.) per day, many patients have taken three or four times this quantity for months without harmful effects. The gluconate and sulfate portions of the molecules are not antagonistic.

Therapeutic doses of iron cause many patients to have epigastric distress and often produce either diarrhea or constipation. These symptoms tend to be more severe if the dose is doubled, but there is no reason to think that a mixture of the two preparations would be more aggravating than would be a comparable amount of ferrous sulfate alone. Some patients, as a matter of fact, seem to tolerate ferrous gluconate better than the sulfate.

The fear has been expressed occasionally that with long continued administration of large doses of iron enough of the metal might be absorbed to have toxic effects on tissues. If this ever occurs, it has not been recognized. Available evidence suggests, furthermore, that the mucosa of the gastrointestinal tract in a major regulator of iron metabolism and can accept or reject iron according to body needs. If this concept is correct, the body protects itself against toxic amounts of iron by refusing to absorb more than it needs.

LATE EFFECTS OF BRAIN INJURY

To the Editor:—A veteran aged 28 incurred a machine gun bullet wound two years ago involving the right temporoparietal area. A tantalum plate covers the skull defect. There is a residual spastic paralysis of the left hand, arm and leg. He has had attacks of unconsciousness which lasted ten to fifteen minutes and recur irregularly at one or two month intervals. These attacks do not have a preceding aura, and the only immediate sequela is nausea for half a day. His history prior to the head injury is entirely negative. What can be done for these attacks?

O. J. Burroughs, M.D., Dongola, Ill.

ANSWER.—The patient has had a bullet injury to his brain with destruction of cerebral tissue resulting in a spastic hemiplegia. He now has attacks of unconsciousness, which are a sign of cerebral irritation just as convulsions are. This irritation may be produced by intracerebral or cortical scar tissue, an accumulation of fluid near the injured area or an abscess. The only way to determine the anatomic results of the injury is by doing pneumoencephalographic studies, which may show whether the attacks are due to scar tissue or to an abscess. The presence of an abscess is always a surgical indication. Depending on their location and depth and the anatomic changes present, scars may also benefit from surgery. However, these procedures may not cure the patient of his attacks of loss of consciousness and these will have to be treated, like convulsive seizures, with anticonvulsant drugs such as diphenylhydantoin sodium, barbiturates or bromides.

RECURRENT ERYSIPELAS-LIKE ERUPTIONS

To the Editor:—Please discuss the prophylactic *treatment of recurrent* erysipelas. Two patients have recurrent attacks in spite of hygienic care of their feet (the infection originates between the toes) and the prophylactic use of *stock vaccines. Sulfonamide* drugs and penicillin have been effective for both during attacks.

J. M. Bodenheimer, M.D., Shreveport, La.

ANSWER.—Recurrent erysipelas-like eruptions, particularly on the lower extremities, are not uncommon and have been the subject of investigation by many workers. In 1926 I. L. McGlasson (Recurrent Erysipelas of the Legs with Dermatitis of the Feet, *Arch. Dermat. & Syph.* **14**:679 [Dec.] 1926) called attention to this condition and presumed that the lesions on the feet and legs were areas of erysipelas or cellulitis caused by the lymphatic transmission of bacteria, usually hemolytic streptococci, which invaded through fissures and erosions of fungous origin.

In Queries and Minor Notes (Recurrent Erysipelas-like Eruptions, THE JOURNAL, July 10, 1943, p. 77) the subject was discussed at length and suggestions were made as to treatment.

In 1944 Morris Waisman (*Arch. Dermat. & Syph.* **53**:10 [Jan.] 1946) read a paper at the Chicago session of the American Medical Association entitled "Recurrent, Fixed Erysipelas-like Dermatophytid." The differential diagnostic points are given as follows: "The streptococcic type of inflammatory eruption of the lower extremities and the erysipelas-like dermatophytid may generally be distinguished by certain contrasting characteristics. Suggesting erysipelas are the following features: (1) longer duration of the attack than generally occurs with the dermatophytid; (2) neutrophil leukocytosis; (3) usual coexistence of higher temperature and more pronounced systemic reaction; (4) successful treatment with sulfonamide drugs, and (5) frequent supervention of fibrosis and lymphedema (elephantiasis) as sequelae of repeated infectious episodes.

The foregoing criteria are the reserve of those associated with the dermatophytid, which usually is manifested by (1) rapid evolution and subsidence, at times within twenty-four or forty-eight hours, (2) leukocytosis inconstant and often absent, (3) afebrile course or one associated with relatively low fever and mild constitutional symptoms, (4) failure of sulfonamide therapy to prevent recurrences and (5) absence of lymphedema, regardless of multiple and frequent recurrences."

Waisman concludes that "recurrent erysipelas lesions on the lower extremities as a complication of dermatophytosis of the feet may be either of bacterial or of fungous origin. In the first instance they are plaques of true erysipelas, the streptococci being transmitted from tineal fissures and erosions by way of the lymphatics. In the second they are an expression of localized hypersensitivity of the skin to fungous products originating from the focus of dermatophytosis."

As the attacks in the 2 cases described in the inquiry yielded to treatment by sulfonamide drugs or penicillin, it is reasonable to assume that the erysipelas-like eruptions were due to bacteria rather than to fungi. Prophylaxis should consist in frequent examination of the feet by the physician. Probably the safest method of continuous treatment to avoid further infection would be soaking of the feet in 1 : 2,000 potassium permanganate solution two or three times weekly. Continuous application of the sulfonamides or penicillin should be avoided because of the possibility of sensitizing the patient to either one or both of the drugs.

ARTIFICIAL LIMBS

To the Editor:—What is the best artificial leg for a midthigh amputation in a man who weighs 180 pounds (82 Kg.) and is 5 feet 11 inches (180 cm.)? Who is the manufacturer? Jospeh J. Lordi, M.D., New York.

ANSWER.—It is impossible to state what is the best artificial leg suitable for a patient with an amputation as described in the query without actually examining the patient. There are many artificial legs for midthigh amputations which are satisfactory prostheses.

The material from which the leg is made has little bearing on its usefulness and efficiency. The skill with which it is fitted and the patience demonstrated by the representatives of the manufacturer in teaching the patient the correct use of the prosthesis constitute the most important factors.

In each of the larger cities there are a number of concerns which assemble artificial limbs under their own trademark. The vacuum socket limb is still in the experimental stage. It is being manufactured by permission of the government agency which developed it by companies in Texas, California, Nebraska and Chicago. This limb is held in place by the suction created in the socket as the air escapes through a special valve. It does not require the use of either shoulder straps or a belt. This limb, however, is not recommended for patients suffering from diabetes, arteriosclerosis, carcinoma or sarcoma with metastases or in whom there has been any infection in the amputation stump. It is ideally suited for a person who has lost a limb as a result of accident, in which there is a well healed and well modeled amputation stump in the middle third of the thigh.

CASTANEDA VACCINE

To the Editor:—Please discuss the use of Castaneda's vaccine for undulant "fever." J. S. Kootsey, M.D., Hot Springs, National Park, Ark.

ANSWER.—The brucella antigen (MBP) that was introduced by Castaneda and Cardenas (*Am. J. Trop. Med.* **21**:185 [March] 1941) apparently is an appropriate vaccine for the treatment of Mexican patients, who suffer chiefly from infection with the melitensis variety. The antigen is composed of soluble materials from all three species of Brucella. Experience is neither large enough nor long enough to permit an accurate appraisal of its value in the treatment of patients infected with the bovine or porcine varieties, the predominant infecting agents in the United States. It has long been recognized that inclusion of the melitensis variety in whole bacterial cell vaccines has made such vaccines less satisfactory for the treatment of patients infected with bovine or porcine strains. The reported Mexican experience with MBP in the treatment of abortus infected patients is encouraging for its small size. There are no reports in the American literature on the use of this vaccine in the treatment of abortus infected patients.

HIBERNATION AND PITUITARY HYPERTROPHY

To the Editor:—An answer to the query of A. J. Alcorn concerning hib nation in animals in The Journal, Jan. 27, 1945, states that the pronoun hypertrophy of the hypophysis during hibernation probably is related the effect of light. What is the source of these investigations on role of changes of day length in the seasonal cycle of hibernating ma mals? Such a relation is doubtful for mammals since they are confir during dormancy in deep burrows, although it is probable for amphibi and fish, which hibernate in ponds and streams.

N. Kalabukhov, Moscow, U. S. S. R.

ANSWER.—Cushing and Goetsch (Hibernation and the Pitu tary Body, *J. Exper. Med.* **22**:25, 1915) reported a hypertrop of the pituitary gland toward the end of hibernation, i. e. befo the action of light could manifest itself. However, A. T. Ra mussen (The Hypophysis Cerebri of the Woodchuck, *Endoc nology* **5**:33, 1921) reported such a hypertrophy only aft awakening and no change during hibernation. There is a di agreement concerning the facts in these two papers.

REMOVAL OF ATROPHIC TESTIS

To the Editor:—A man aged 30 was operated on at 20 years of age for undescended testis. The testis was placed in the scrotum but has fail to grow. At present he complains of vague pain in the region of t testis. The right testis is the size of a marble and slightly tend The left testis is normal. Should this small functionless testis be remove (The patient is neurasthenic and has been told that an operation necessary.) Is there a greater than average danger of malignancy?

B. H. Scott, M.D., Mont[illegible]., Canada.

ANSWER.—The removal of a small atrophic testis which causing pain is a minor operation and can be carried out wit ease under local anesthesia. The procedure is justified if pai is present. However, in psychoneurotic persons there is ofte a fixation on the genital apparatus. Testicular pain is commonl a manifestation of a conversion, especially if the patient's atten tion has previously been called to the fact that there is somethin wrong with his testis. Following the removal of such an orga the pain may persist or be aggravated with localization in th stump of the spermatic cord or higher up in the inguinal cana Therefore the decision to operate may be a difficult one to mak and depends on judgment in the individual case.

The incidence of cancer is greater in the cryptorchid than i the normal testis. This hazard is not entirely eliminated b orchiopexy, since neoplasms occur in testes which previousl have been subjected to operation. However, the incidence o cancer in a testis such as the one described in the query is no sufficiently high to justify its removal for this reason alone.

RECURRENT BUCCAL VESICLES FROM DENTURE

To the Editor:—A white woman aged 64 has had recurring vesicles of th buccal mucous membrane for the past thirteen months. These vesicle are always situated on the right buccal mucous membrane above th right gum line. The vesicles usually run a complete cycle of eleven day after which time they are healed and a new crop appears. The patien is edentulous and wears dentures. All tests, smears and cultures have bee negative. She has been treated by at least twelve other physicians withou improvement. Recently she was given intensive treatment with vitamin complex orally and intravenously for six weeks, along with large dose of thiamine hydrochloride and ferrous sulfate. There was no improvement Please discuss the diagnosis and treatment. M.D., Indiana.

ANSWER.—The oral tissues of a person who wears a dentur may react to the denture. The person may be sensitive to th materials used in the construction of the denture or, if th denture does not fit well, it may be a source of mechanica irritation. The oral manifestation of a dermatologic vesicula condition should also be considered.

In regard to treatment the denture should not be worn fo several weeks to see whether the lesion will disappear. A patch test should be done and the denture checked for mechanica adjustment.

OSTEOGENESIS IMPERFECTA

To the Editor:—What is the present accepted treatment for osteogene imperfecta? Is it safe to advise a couple to have more children wh their first child has a severe form of osteogenesis imperfecta congenit

M.D., North Carolina.

ANSWER.—An accepted treatment for osteogenesis imperfec has not been perfected. This condition is hereditary in son instances, but unless there is a definite family history of t condition there is no reason why a couple should not have ot children when the first child has a severe form of osteogene imperfecta congenita. In mild cases the prognosis is improvement as the child grows older. General hygienic m sures are important, with high calcium and high vitamin There is no specific medication that can be called curativ
